15. ORTHOPEDIC SURGERY

Type of training acceptable to Board: A—Adult orthopedics; C—Children's orthopedics; F—Fractures. The following services have been approved by the Council and the American Board of Orthopedic Surgery, through the Residency Review Committee for Orthopedic Surgery, as offering acceptable training in adult orthopedics, children's orthopedics, and fractures. Training in the basic sciences is given either as an integral part of these services or as a separate course. Services collaborating in an integral plan of training are designated by a program number, a list of which is found on pages 318-319.

Residents completing their training in these hospitals are eligible for full certification by the American Board of Orthopedic Surgery, including children's orthopedic surgery.

Hospitals, 198; Assistant Residencies and Residencies, 807

The following services have been approved by the Council and the American Board of Orthopedic Surgery, through the Residency Review Committee for Orthopedic Surgery, as offering acceptable training in adult orthopedics and fractures. Training in the basic sciences is given as an integral part of these services or as a separate course. Services collaborating in an integral plan of training are designated by a program number, a list of which is found on pages 318-319.

Residents completing their training in these hospitals are eligible for limited certification by the American Board of Orthopedic Surgery, not to include children's orthopedic surgery.

15. ORTHOPEDIC SURGERY—Continued

The following services are approved by the Council and the American Board of Orthopedic Surgery, through the Residency Review Committee for Orthopedic Surgery, as offering acceptable training in one or more but not all categories of orthopedic surgery. Hospitals included in this list are urged to develop a full three year program, either independently or in collaboration with other institutions in order to assure applicants for appointment of an opportunity for completing their training with progressive graded responsibility.

17. PATHOLOGY

The following services have been approved by the Council and the American Board of Pathology. Services which have been evaluated on the basis of training in the two categories, pathologic anatomy and clinical pathology, are designated as follows: a—pathologic anatomy only; c—clinical pathology only; p—pathologic anatomy and clinical pathology. Training in hospitals which are not so designated in this list will be evaluated by the Board on an individual basis at the time of application for certification.

State of Washington	Seattle	B. Bucove	King-Seattle	771,100*	$500
			Clark-Skamania	90,400*	....

---

* Estimated.

(a) Excludes Alameda, Berkeley, and Oakland cities with full-time health officers, and Albany and Livermore with part-time officer.

(b) Excludes the city of Wilmington.

(c) To those planning to work in state; transportation costs only to others.

(d) Excludes Berwyn, Chicago, Evanston, Oak Park, Stickney Township, and Winnetka (including Glencoe, Kenilworth, Northbrook, and remainder of New Trier Township), all with full-time health officers.

(e) Assistance can be arranged for securing the MPH degree in the midst of, or after completion of, residency experience. Appointments normally are limited to those training for service in Illinois.

(f) Arrangements for remuneration made on an individual basis.

(g) Arrangements for remuneration made upon determination of field of interest and location desired.

(h) Training is given in a combination of one county, one union health, and seven municipal health departments and in the divisions of the State Department of Health.

(i) To those training for service in Massachusetts only.

(j) Excludes Detroit and Dearborn, each with full-time health officers.

(k) To those training for service in Minnesota only.

(l) Training is given in any one of 10 city health departments, 16 county health departments, or 15 district offices within the state.

(m) Training to be with Michigan Department of Health, with field experience in local health departments.

22. PROCTOLOGY

The following services have been approved by the Council and the American Board of Psychiatry and the Residency Review Committee for Proctology, as offering acceptable training in the specialty.

Hospitals, 12; Assistant Residencies and Residencies, 22

PSYCHIATRY PROGRAM IDENTIFICATION

10. Service in child psychiatry.
11. Six months service at Los Angeles County Hospital, Los Angeles.
12. Nine months service at Mount Zion Hospital, six months at Langley Porter Clinic and service in child psychiatry, San Francisco.
13. Three months of service at Napa State Hospital, San Francisco Hospital, Stricktou State Hospital, Sonoma State Home and San Quentin Prison; and six months at Colwell Memorial Hospital.
14. Three months service Fort Miley Veterans Adminisration Hospital, San Francisco, and Langley Porter Clinic, San Francisco; may include elective services at University of California Hospital, Mount Zion Hospital and Stanford University (Lane) Hospital, San Francisco.
15. Three months service at Pacific Colony Hospital, Spadra, and three months service in child psychiatry at Camarillo State Hospital.
16. Affiliate services at Colorado General and Denver General Hospitals.
17. Affiliate service at Veterans Administration Hospital, West Haven Connecticut State Hospital, Fairfield State Hospital, Norwich State Hospital and service in child psychiatry.
18. Twelve months service at Grace-New Haven Community Hospital, New Haven, Connecticut.
19. Six months service at Governor Bacon Health Center, Delaware City.
20. Two months service at George Washington University Hospital, Washington, D. C.
21. Affiliate service at University Hospital, Augusta, Georgia.
22. Twelve months service at the Neuropsychiatric Institute of the University of Illinois including service in child psychiatry.
23. Eighteen months affiliate service including service at the Neuropsychiatric Institute of the University of Illinois and three months in child psychiatry.
24. Affiliate service at Neuropsychiatric Institute of the University of Illinois and service in child psychiatry.
25. Three months service at Veterans Administration Hospital, Downey, Illinois, and service in child psychiatry.
26. Six months service at Veterans Administration Hospital, Hines, Illinois. May include service in child psychiatry.
27. Six months service in child psychiatry.
28. Integrated program including service at Veterans Administration Hospital, Indianapolis General Hospital and Indiana University Medical Center and Affiliated Hospitals, Indianapolis.
29. Integrated program including service at Veterans Administration Hospital, Menninger Sanitarium and Topeka State Hospital, Topeka, Kansas.
30. Four months service at University of Louisville Services, Louisville, Kentucky, and four months service at Cincinnati General Hospital, Cincinnati, Ohio.
31. Three months service at University of Louisville Services, Louisville, Kentucky.
32. Twelve months service at University of Louisville Services. May include four months service at Central State Hospital; four months service at Louisville General Hospital.
33. Four months service at Central State Hospital and service in child psychiatry.
34. Integrated program including service at Tulane University Unit, Charity Hospital, New Orleans, and Veterans Administration Hospitals, New Orleans, and Gulfport, Mississippi.
35. Six months service in child psychiatry and twelve months service at South Louisiana State Hospital.
36. Service in child psychiatry; six months service at Veterans Administration Hospital, Perry Point, Maryland.
37. Three months service in child psychiatry at Johns Hopkins Hospital (Harriet Lane House), Baltimore, Maryland.
38. Twelve months service at Boston State Hospital and service in child psychiatry.
39. Twelve-eighteen months service at Veterans Administration Hospital, Boston (Jamaica Plain), Massachusetts, and six months service in child psychiatry.
40. Integrated program including service at Massachusetts General Hospital and McLean Hospital, Waverly.
41. Twelve months service at University Hospital, Ann Arbor, Michigan.
42. University Hospital, Ann Arbor, Michigan.
43. Three months service Coldwater State Home and Training School, Caro State and Ionia State Hospitals and service in child psychiatry.
44. Six months service in child psychiatry at Children's Hospital, Detroit.
45. Six months service at Receiving Hospital, Children's Hospital, Detroit, and Wayne County General Hospital and Infirmary, Eloise, Michigan.
46. University of Minnesota Hospitals, Minneapolis, Minnesota.
47. Three months service at Rochester State Hospital, Rochester, Minn.
48. Affiliate service at Barnes Hospital, St. Louis and three months at St. Louis State Hospital.
49. Six months service at Barnes Hospital, St. Louis, Missouri.
50. Service at St. Louis State Hospital and St. Louis City Hospital.
51. Service at Lutheran Hospital, Omaha.
52. Service at University of Nebraska Hospital.
53. Affiliate service at University of Nebraska Hospital and Creighton Memorial-St. Joseph Hospital, Omaha, Nebraska.
54. Six months service at Newark City Hospital; three months at New Jersey State Hospital and three months in child psychiatry.
55. Three months service at Albany Hospital, Albany, New York.
56. Affiliate services at Edward J. Meyer Memorial Hospital and Buffalo State Hospital.
57. Six months service at King's County Hospital, Brooklyn, New York.
58. Integrated program with service at Bellevue Hospital Center and University Hospital.
59. Six months service at Mount Sinai Hospital, New York City.
60. Service in child psychiatry. May include six months service at Mount Sinai Hospital and three months at Manhattan State Hospital.
61. Twelve months service at New York Hospital and four months at Veterans Administration Hospital, New York City (Bronx), New York.
62. Three months service at Grasslands, Rockland State, Albany Hospitals and Letchworth Village.
63. Six months service at Rochester State Hospital, Rochester, New York.
64. Six months service at Strong Memorial-Rochester Municipal Hospitals, Rochester.
65. Affiliate service at Strong Memorial-Rochester Municipal Hospitals.
66. Three months service at Syracuse Memorial, Binghamton, Syracuse and Willard State Hospitals, service at Craig Colony and service in child psychiatry.
67. Affiliate service at State Hospitals at Raleigh and Butner, North Carolina.
68. Eighteen months service at Duke Hospital, Durham, North Carolina.
69. Three months service at Longview State and Jewish Hospitals, Cincinnati.
70. Integrated program including service at Cleveland Clinic and Windsor Hospital.
71. Integrated program including service at University Hospital and Veterans Administration Hospital, Cleveland, Ohio.
72. Integrated program with service at Institute of the Pennsylvania Hospital and Pennsylvania Hospital Department for Mental and Nervous Diseases.
73. Affiliate services at Temple University Hospital, Institute of Pennsylvania, Hospital of the Woman's Medical College of Pennsylvania.

Numerical and other references will be found on page 363.

PSYCHIATRY PROGRAM IDENTIFICATION—Continued

74. Six months service at Philadelphia General Hospital and service in child psychiatry.
75. Two months affiliate service for institutional care.
76. Integrated program including service at Vanderbilt University Hospital, Veterans Administration Hospital, Nashville, Veterans Administration Hospital, Murfreesboro, and Central State Hospital, Nashville.
77. Four months affiliate service at St. Mary's Infirmary, Galveston, Texas.
78. Service in child psychiatry at *Jefferson Davis Hospital, Houston,* Texas.
79. Six months affiliate service at Veterans Administration Hospital, Salt Lake City, Utah, and affiliate services at State Hospital, Provo, Utah.
80. Integrated program including service at University of Virginia Hospital, Charlottesville and Veterans Administration Hospital, Roanoke, Va.
81. Affiliate service at Southwestern State Hospital, Marion and Lynchburg State Colony, Lynchburg, Va.
82. Six months service at Medical College of Virginia—Hospital Division, Richmond, and service in child psychiatry.
83. Six months service at Veterans Administration Hospital, American Lake, Washington, and six months in child psychiatry.

24. PULMONARY DISEASES

The following services have been approved for one year of training by the Council and the Subspecialty Board for Pulmonary Diseases of the American Board of Internal Medicine.

ANNUAL REPORT ON INTERNSHIPS AND RESIDENCIES

The Council on Medical Education and Hospitals presents in this issue its 29th Annual Report on Internships and Residencies. The report is factual in nature and presents statistical data on the number of internships and residencies in hospitals throughout the country, as well as general information on committees active in the field of graduate education, on the National Intern Matching Program, and on other related subjects. The report is based on data supplied by 1,364 hospitals in the United States and its possessions in which approved training at the graduate level is being conducted. Some of the statistics presented are of particular interest, reflecting the extent to which graduate education has developed in this country. One such statistic is the total number of physicians serving as house staff members; there were, according to the report, 9,066 graduates serving internships as of September 1, 1954, and 20,494 serving as residents, or a total of 29,560. When one considers that this figure exceeds the number of students enrolled last year in all our medical schools, one can appreciate more clearly the magnitude of the growth of graduate training over the past 10 years. In terms of persons involved and of time spent, the graduate phase of medical education has now come to occupy a place comparable to that at the undergraduate level.

The percentages of positions filled last year increased for both internships and residencies. While the increase was small, 4% for internships and 1% for residencies, it did reverse the downward trend of the past several years. The report points out that the increase was due, in large part, to the greater number of graduates of foreign medical schools serving in approved hospitals. While their presence alleviates to some extent the demand for house staff appointees, it is apparent that in partially solving one problem on this basis, others have been created. The report notes that a Cooperating Committee on Evaluation of Graduates of Foreign Medical Schools has been established to consider these problems as they affect standards of medical education. The Council and the agencies with which it cooperates, as well as the medical staffs and administrative heads of the hospitals contributing to this annual report, are to be commended for making available to the profession and others interested in medical education, this comprehensive compilation of information on a phase of medical education that continues to grow in importance.

"FULL TRAINING" REQUIREMENT FOR RESIDENCY APPROVAL

In this issue (page 382) there are several announcements made regarding future policy relative to approval of residency training in four specialties. In all of these announcements, the same principle is applicable; i. e., hospitals, to qualify for continued approval, are required to provide "full training" in the specialty, either independently or in collaboration with other hospitals through integration of their programs. In considering this development, the history of the residency approval program, particularly during the past 10 years, is pertinent. Prior to 1945, there were about 5,000 residency positions available in approved hospitals throughout the country. This figure included appointments at all levels—first, second, and third year positions. In the immediate postwar period there was a tremendous demand for residency training, particularly from medical officers being released from military service. Hospitals that had been conducting residency training expanded their programs to take in additional residents, and many hospitals that had not previously attempted to train residents were encouraged to initiate such programs. As a result, the number of residencies increased at an unprecedented rate until now there are roughly five times as many residency positions available as there were 10 years ago.

In retrospect, the soundness of the overexpansion of training facilities can be questioned. At the time, however, the policy of encouraging the development of new programs and the enlargement of those already in existence was justifiable. Had this marked inflation of the residency system not taken place, a large number of applicants would have been denied additional training and would, perforce, have had to return to practice without the opportunity to enhance their professional knowledge and background in the field of their choice. There are those who take the position that many of the hospitals that entered the field of residency training during those years were not in a position to provide the type of training considered optimal. With this generality, one cannot perhaps quarrel. One may raise the question, however, as to whether the public interest was not better served under a program in which the maximum number of physicians received additional training in preparation for civilian practice than under a more restrictive policy through which a relatively limited number of physicians would have had the opportunity for a more intensive and perhaps higher quality of residency training.

In any event, a number of residencies were approved during the past 10 years for periods of training varying from one to four years. Under policies that have been applicable in the past, a resident could take his training in two or three such separate programs and qualify for board examination in the specialty. A not too inaccurate analogy would be one in which a medical student would be able to qualify for his doctorate degree through having completed four successive years at the freshman level in four different medical schools. To obviate this possibility, and to assure that residents finish their training with some degree of continuity of supervision and of increasing, graded responsibility, a number of the committees responsible for evaluating and approving residency programs have adopted the policy that hospitals offering residencies in these specialties should provide full training for their residents either by developing independently a complete training program or by integrating their residency with one or more other hospitals that by combining their resources can provide full training in the specialty. The validity of this policy from an educational standpoint is difficult to refute. It will, of course, result in some hospitals having to discontinue their programs unless they can meet the requirement for complete training. In the interest of improving the standards of graduate medical education, however, and of the residents themselves, the policy as adopted by the residency review committee is eminently sound.

"ANNUAL" APPROVAL FOR RESIDENCY TRAINING

The number of hospitals approved for residency training has remained relatively constant for the past few years. There have been of course, some changes in the status of these institutions as new programs are approved and others are dropped from the list of recognized services. In the latter instance, there is quite apt to be a fairly strong reaction on the part of the medical staff and administration of the hospital concerned. One of the reasons for the protests that occasionally result when approval is terminated is the misconception that once approval is granted it is more or less permanent. In effect, approval of a residency program is granted on an annual basis through inclusion in the list of services that appears in the Internship and Residency issue of The Journal. Approval of a program is continued automatically until there is a change in the service such as the appointment of a new department head or until such time as the program is resurveyed. These surveys are made every two to three years and the findings referred to the appropriate reviewing committee. Their evaluation of the program is based on the report of inspection as developed by the staff representative of the Council and on the data submitted by the hospital. Continued approval is considered warranted only when it is evident that standards for training are being met. Approval is not continued, however, simply on the basis that the residency had been approved in the past.

A residency program should be constantly reappraised by the medical staff itself, if only to assure that the program's objectives are being met. Unless such periodic self-evaluations are made, it is quite likely that the program will deteriorate and on survey will be found to have deficiencies that may be considered serious enough to result in withdrawal of recognition. A fairly reliable, if somewhat homely guide in evaluating the adequacy of a program, is whether it is a service that one could recommend unqualifiedly to someone seeking one's best advice. If so, there need be little concern over continued approval of the program. If not, there is need for corrective action that might well be taken as a preventive measure prior to, rather than after, the evaluation of the approving committee. As in medicine, the ounce of prevention may well be worth the pound of cure.

BOSTON CLINICAL MEETING

The Clinical Meeting of the American Medical Association to be held in Boston, November 29 to December 2, 1955, marks the ninth assembly of this winter feature. Since its inauguration in Cleveland in January, 1948, the clinical meeting has developed a distinctive pattern and has become an outstanding contribution to graduate medical education. Predictions for the Boston meeting indicate one of the largest clinical meetings on record. The program will soon be ready for publication. Lectures and round-table discussions, arranged by the local committee in Boston and covering all phases of medicine, will be conducted in three lecture halls simultaneously and continuously, thus giving the visiting physician a varied group of subjects from which to choose. Color television, originating at New England Deaconess Hospital, will bring the operating room into the lecture hall. The local committee is arranging an outstanding program of both medical and surgical subjects. A carefully selected list of motion pictures, in some cases supplementing other features of the program, will be shown continuously, with many of the authors present to discuss their films. The Scientific Exhibit will be as attractive as ever, with outstanding authorities continuously available to answer questions and discuss problems with other physicians. Special mention should be made of the fracture exhibit and the manikin demonstrations on problems of delivery where experts will be available for consultation. The Technical Exposition, where all leading medical supply houses will be represented, will show visitors what is new in equipment, books, and pharmaceuticals. All scientific activities will be held in the Mechanics Building. This historic structure will fit the purposes of the meeting comfortably. The House of Delegates will be meeting meanwhile in the Statler Hotel. Boston is always interesting to visit, having many historic and modern attractions. Lexington and Concord are nearby. The program of this meeting, built against an absorbing background of medical history, will make the 1955 clinical meeting doubly worth while.

THE PRESIDENT'S PAGE

A MONTHLY MESSAGE

I am often told that the younger practitioners are more or less responsible for much of the dissatisfaction that exists in the minds of the public concerning medical fees. I also have heard many people say that the older physicians are more understanding when it comes to charges for medical services but that many of the younger men aspire too rapidly for financial success and security for themselves and their families. However, I am satisfied that the over-all attitude of the younger men is substantially good and that most of them only wish to be received and treated fairly in the communities where they have elected to settle and practice. It must be remembered that the average young physician has little chance to earn a living until his late 20's and early 30's. Let us for a moment look at his education and its cost. The average boy graduates from high school at about 18 years of age. The cost of four years of college and medical school is about $6,000 just for his education. This does not include his room and board nor his loss of earnings during this period of eight years. This alone would amount to approximately $24,000 for the period. The total cost then for an M.D. is approximately $38,000. Then at least one year's internship is necessary. Here for the first time he may receive a small remuneration. According to conservative estimates then the current cost of becoming a physician starting practice at age 30 is at least $52,000, and the physician will need $7,000 of gross fees every year for 35 years to amortize his investment. During the process of their academic education many of these young men acquire wives and one or more children, all of which add to their need for making a living as well as practicing a legitimate profession.

It is a difficult thing for me, after traveling the length and breadth of this grand country of ours, meeting actually thousands of these younger practitioners, to believe that their sole interest is money and that they have little or no regard for the financial and economic problems of their patients. However, there is another problem concerning these younger men that does disturb me a great deal. Let us now carry one of these younger men through a residency training program where he is fitting himself for a speciality. Here the problem becomes greatly complicated and much more difficult. After an internship the youthful physician, the wife and children in many instances, accepts a three or five year approved residency in one of the specialities. He may receive a small salary, but it is seldom sufficient. Certainly he does not in any sense earn enough to cover his expenses. Some speciality boards make him practice his speciality for a minimum of two years after completion of his residency. Attached to this obligation to make him eligible for his examinations is the penalty of forfeiting his right to take his boards if he practices anything but the specific speciality for which he has trained. In other words, he cannot, if preparing for his surgical boards, treat medical cases. If the young surgeon can associate himself with an older, well-established surgeon, his road to the examinations is relatively easy, but, if he elects solo practice, his road is hard and thorny unless he is personally well off financially. He finds that while he is excellently trained, patients of other established physicians are not going to rush to him for surgery. They look upon him as inexperienced, and he has a difficult time in getting established.

Since economic factors are very important, and the small family is hungry and no work shows up, he finds himself beset with many problems. The most important is—"Can I remain ethical and stick it out?" Of course I say he can, but some men so harassed are sorely tempted. The problem is simply an economic one. Fee splitting and other obnoxious procedures may become a great temptation. Strong must be the character of the specialist if he is to resist temptation. I am convinced that the majority of these men are of strong character. It takes at least two to make a bargain. There are many economic urges that could make the deal seem justifiable, but once the deal is made the die is cast for the future. I sometimes think that our specialty boards are too severe when they do not permit the young specialist to treat any patients except those that fall into his special field during these first trying years of practice. It is my opinion that a specialist is first a physician, and I am sure that, with the present demand for good physicians, these young specialists will be able to brave the economic storm and come up unscathed. Doctors have faced difficulties before and overcome them. They can do it again.

Youthful physician, youthful specialist, the future of medicine is in your hands. We believe in you.

Elmer Hess, M.D.,
Erie, Pa.

ORGANIZATION SECTION

FEDERAL MEDICAL LEGISLATION

First Session, 84th Congress

Disability Insurance for Employees in District of Columbia

Senators Case (R., N. J.), and Ives (R., N. Y.) have introduced S. 2753, the administration's proposal to establish a mandatory system of cash payments for temporary disability of workers in the District of Columbia. Disability is defined as "the inability of an individual as a result of his physical or mental illness, disease, or injury to perform his most recent, customary, or reasonably similar work," and would not be necessarily due to his employment. The benefits would be half of the individual's average wage, with a maximum of $36 and a minimum of $12, and could not be collected for more than 26 weeks within a 52 week period. The benefits would be financed by a payroll tax. The employee's contribution could not exceed 0.5% of his earning, or 30 cents per week, whichever is the lesser. Employers could use an insurance program or contract with an employee union or corporation for coverage. If the payroll is less than $20,000 annually the employers could use a special District of Columbia insurance fund for coverage. This bill was referred to the Committee on the District of Columbia.

Dependent Medical Care for the Military

Congressman Price (D., Ill.) by request has introduced a measure designed to set up a voluntary health insurance program for military dependents, with nonprofit plans (Blue Cross) to be used in every case where such service is available. The federal government would bear the full cost of the premium, and no charge could be made for costs in military facilities except for subsistence. This measure was referred to the Committee on Armed Services.

Hospital Reading Matter

Congresswoman Green (D., Ore.) proposes, in H. R. 7841, to authorize the Post Office Department to give "unclaimed or undeliverable books, newspapers, magazines, and other publications" to hospitals, asylums, or reformatory institutions. Delivery would be effected without cost to the United States. This bill was referred to Committee on Post Office and Civil Service.

Surplus Property for Hospitals, Clinics, and Health Centers

Congressman Ellsworth (R., Ore.), in H. R. 7425, would authorize donations from the general services of surplus property found usable and necessary for educational or Public Health purposes, including research, to nonprofit and tax-supported medical institutions, hospitals, clinics, health centers, and colleges. This measure was referred to the Committee on Government Operations.

Services to Aging

Senator Wiley (R., Wis.), in S. 2279, would authorize grants to states for planning and programs for services to the aging. This measure would authorize 2 million dollars for planning grants and 10 million dollars the next year for programs and such sums thereafter for three years as Congress desires. The program would be under the supervision of the Secretary of Health, Education, and Welfare, and would be administered in each state by a single agency. This bill was referred to the Committee on Finance.

Federal Scholarship Act

Congressman Multer (D., N. Y.), in H. R. 7846, would authorize loans to enable needy and scholastically qualified students to continue education after high school, including premedical. A federal trust fund would be established with 4 million dollars the first year and 10 million dollars the second. The program would be administered by the Commissioner of Education, who would select the students certified to him by the state agency. The state contribution would vary from 5% to 10% of the amount of the scholarships. This measure was referred to the Committee on Education and Labor.

Prepared by the Washington Office of the American Medical Association.

NEW TELEVISION AIDS

Two new television "scripts-with-film" programs featuring health education information on the eye and its functions will be released this fall by the A. M. A. Prepared with the cooperation of the A. M. A.'s Bureau of Health Education and the National Society for the Prevention of Blindness, these shows are designed so that a local physician can narrate while the film is thrown on the television screen. The programs are: (1) "A Clear Picture"—which deals with the eye and its functions and includes an animated sequence employing a fresh orange, a glass lens, and a piece of lipstick to show the structure of the eye; and (2) "Wonderful Spectacle"—which describes the functions of glasses and lenses. The programs are so constructed that they can be used as separate 15 minute programs or together as a single 30 minute presentation. The film demonstrator is Dr. Brittain F. Payne of New York City, an ophthalmologist. Films and accompanying scripts will be available about Sept. 15 through the A. M. A. TV Film Library. There is no charge to medical societies.

QUARTERLY CUMULATIVE INDEX MEDICUS

Volume 53 (Jan.-June 1953) of the Quarterly Cumulative Index Medicus is now available. Orders for copies should be addressed to the Order Department, 535 N. Dearborn St., Chicago 10, Ill.

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

POLICY RELATING TO APPROVAL OF RESIDENCY PROGRAMS

The Council on Medical Education and Hospitals wishes to make the following policy announcements relating to approval of residency programs. The statement on basic sciences in an approved surgical residency has been adopted by the Conference Committee on Graduate Training in Surgery, representing the Council, the American Board of Surgery and the American College of Surgeons. Statements regarding the discontinuance of approval for "partial" training in a number of the specialties have been adopted by the Residency Review committees for the specialties concerned. These committees represent the Council and the respective examining boards in approving residency programs. A similar announcement relating to residency programs in pediatrics appeared in the April 10, 1954, issue of THE JOURNAL (page 1303). Approval for residency training in anesthesiology, general surgery, otolaryngology, and plastic surgery, as well as in medical subspecialties, allergy, cardiovascular diseases, gastroenterology, and pulmonary diseases, has for some time been limited to hospitals offering full training, either independently or in collaboration with other hospitals.

STATEMENT ON BASIC SCIENCES IN AN APPROVED SURGICAL RESIDENCY

A fundamental concept of an approved residency in general surgery requires that the program provide for properly organized, integrated and progressively graded clinical training in the specialty. The Conference Committee on Graduate Training in Surgery interprets this concept as requiring a continuity of clinical experience under the supervision of the surgical staff of the hospital or hospitals in which such training is conducted. Accordingly, the Conference Committee while recognizing the value of formal courses in the basic sciences, will not accept these courses as part of a three or four year program, in lieu of clinical experience. When provision is made for the resident to attend such courses, they will be accepted by the American Board of Surgery as credit toward the practice requirement, in addition to an approved three year residency. An approved four year residency may include a research project or an assignment to a basic science department such as pathology, provided that this part of the program has been approved by the Conference Committee. The final year of a four year program, however, must be spent in clinical surgery in the parent institution. The above provisions will be considered effective on and after July 1, 1956, for all residencies in general surgery approved by the Conference Committee, representing the American Board of Surgery, the American College of Surgeons, and the Council on Medical Education and Hospitals of the American Medical Association.

RESIDENCY REVIEW COMMITTEE FOR ORTHOPEDIC SURGERY

At a recent meeting of the Residency Review Committee for Orthopedic Surgery, representing the American Board of Orthopedic Surgery and the Council on Medical Education and Hospitals, the Committee reviewed its policy relative to the approval of training programs of less than three years' duration, i. e., programs offering training in one or more but not all aspects of the specialty. It was the considered opinion of the Committee that hospitals should provide for an opportunity for full training, either intramurally or through affiliation in order to assure fully integrated educational experience with continuity of supervision of the resident staff. Accordingly, the Committee will have serious reservations about continuing approval of those programs offering "partial" training beyond June 30, 1956, unless the hospitals concerned can develop a complete residency training program to include adult orthopedic surgery, fractures, basic sciences, and, if possible, children's orthopedic surgery. This action is in accordance with the policy that has been announced for the past several years, encouraging the development of full three year programs in the listing of approved services in the Internship and Residency issue of THE JOURNAL, Sept. 25, 1954, page 375.

RESIDENCY REVIEW COMMITTEE FOR RADIOLOGY

At a recent meeting of the Residency Review Committee for Radiology, representing the American Board of Radiology and the Council on Medical Education and Hospitals, the following policy was adopted. 1. Effective immediately, hospitals and institutions making initial application for approval for residency training in radiology must qualify for full three year approval. No new residencies of one or two year duration will be approved unless they are integrated with or contributory to a fully approved program. 2. All hospitals and institutions approved for residency training in radiology are expected to develop programs offering complete training, either intramurally or through affiliation, by June 30, 1957. The Residency Review Committee representing the American Board of Radiology and the Council on Medical Education and Hospitals has been established to act in behalf of these two organizations in approving residency programs in this specialty. The present policy relating to future approval for full training only has been adopted to insure that residents receive integrated training with graded responsibility and continuity of supervision during their three year residency. The requirement of a fully organized program in qualifying for approval is in accord with sound educational principles as adopted in several other specialty fields. The Committee does not believe it to be in the interest of the resident that he be permitted to take a year or more of isolated training in two or three unrelated programs in qualifying for board examination. The Committee has had the assurance of the board that residents who have accepted appointment to programs that are presently approved for less than three years will receive full credit for their training on the basis of the residency's present status, through June 30, 1957.

RESIDENCY REVIEW COMMITTEE FOR UROLOGY

At a recent meeting of the Residency Review Committee for Urology, the following policy was adopted. 1. Effective Oct. 1, 1955, hospitals making initial application for residency training in urology must qualify for three year approval (i. e., no new approvals for either one or two years will be granted). 2. Those hospitals now approved for residency training that are resurveyed after the above date must qualify for three year approval or lose their approved status. 3. All hospitals must have qualified for three year approval by July 1, 1957. Up to this date hospitals offering two year programs will have the opportunity to reorganize their programs and qualify for three year approval. Hospitals offering or that are able to offer only one year of training will have the opportunity to become affiliated with another institution that has a fully approved three year program. This committee with representatives from the American Board of Urology and the Council on Medical Education and Hospitals of the American Medical Association has been established to review and pass upon applications for approval of residency training in urology, acting in behalf of the two parent organizations. In adopting the present policy, the committee has had the assurance of the American Board of Urology that residents currently serving and residents appointed to begin their service on or before July 1, 1955, in such hospitals approved for one or two years will receive credit for such training even if the approval status of the program may be terminated at a time prior to completion of the academic year in which they are serving. The American Board of Urology will also continue to grant credit for training in hospitals presently approved at the one or two year level whose programs are not reevaluated on the basis of surveys during the residency year 1955-1956. This policy was adopted to insure that residents receive integrated training during their three year service, with graded responsibility and continuity of supervision. The requirement of a fully organized three year program is in accordance with the principle that has been adopted in other specialties of granting approval only on the basis of a fully organized program.

MEDICINE AND THE LAW

MEDICOLEGAL SYMPOSIUMS

Early in April the physicians and attorneys in Cortland County, New York, met together and heard a discussion by Albert Averbach, of the Seneca Falls, N. Y., Bar, on mutual problems, responsibilities, and attitudes. This experience, which was described in a recent letter from Mr. Averbach, is a relatively new and increasingly popular form of meeting that the Law Department feels is worthy of comment.

Last December Mr. George Hall, a staff member of the department, prepared an article for the *Illinois Bar Journal* with the optimistic title, "Let's Understand Each Other." In reference to meetings such as Mr. Averbach describes, the article states ". . . These meetings bring together the local lawyers and doctors for an evening of sociability and a discussion of some of their mutual problems. It would be a fine thing if such meetings could be held at least once a year in every county in the state. The result of these meetings is an understanding of each other's problems. Perhaps it would not furnish a witness for a particular case, but it will help each profession to respect the aims and attitudes of the other. . . . To the extent, also, that the attorney, by education, becomes aware of the physician's fears and problems, he will be able to approach the physician more tactfully and with better chance of success. If this article does nothing else, it is hoped that it may inspire the holding of medical society-bar association meetings at local level throughout the state. The results are sure to be gratifying to both professions and beneficial to patients and clients alike."

At about the same time another article appeared in the *New York State Journal of Medicine* under the title of "Doctors, Lawyers, and Injured Brains" in which Dr. Sands of Brooklyn, N. Y., said: "There should be mutual respect of physicians and lawyers for the responsibilities and attitudes of each other. This would prove a positive contributing factor to judicial verdicts. . . . Appreciation and respect of each others attitudes and responsibilities would contribute a better relationship between doctors and lawyers."

The American Medical Association has long been cognizant of the desirability of improving better professional relationships between physicians and attorneys. As early as 1944, its then Bureau of Legal Medicine and Legislation said in an annual report to the House of Delegates: "Periodic programs of this type, attended by members of the bar and by physicians, will result in a much needed diffusion of information in this important field." And in its final report last year, the Bureau said: "There seems to be evidenced a trend toward more frequent meetings of this sort. This is a healthy development that should be nurtured by medical and legal organizations." The trend referred to is not only apparent, it is real. The urgings of the American Medical Association, its Committee on Medicolegal Problems, and of others in this field are continually bearing more abundant fruit.

Since the creation of the Law Department last August, activity along this line has been intensified and staff members have participated in joint meetings at other places and most recently at Great Falls, Mont.; Appleton, Wis.; Dubuque, Iowa; Carbondale, Ill.; Oklahoma City; Minneapolis; Madison, Wis.; Springfield, Ill.; Toledo, Ohio; and Knoxville, Tenn.

What may well prove to be the A. M. A.'s most important contribution to date in the field of legal medicine is a series of Medicolegal Institutes that the Law Department and the Committee on Medicolegal Problems will sponsor next fall. Like the custom of prior years, the Committee on Legislation is planning six regional legislative meetings. Three of these meetings will be held on Saturdays in Chicago on Oct. 8, in Omaha on Oct. 15, and in New York City on Oct. 29. On the three Sundays that follow, Oct. 9, Oct. 16, and Oct. 30, the Law Department will sponsor all-day sessions, discussing various medicolegal problems of interest to, and open to, the physicians and attorneys in the particular area. Definite programs have not as yet been worked out, but the Law Department sincerely hopes and believes that these programs will be both interesting and informative.

The experience of the physicians and attorneys in Cortland County, New York, is being duplicated in many parts of the country. The snowball is growing larger. Physicians and attorneys will understand each other, they will improve their professional interrelationships, and society and the administration of justice will benefit from their efforts in this regard.

MEDICAL NEWS

CALIFORNIA

Course in Pathological Physiology.—University of California Extension in Los Angeles will open a course in pathological physiology to graduates of approved medical schools, Mondays, 7:30-9:30 p. m., Oct. 3-Dec. 19, in the third floor lecture room (33-103) of the University of California Medical Center, Los Angeles. The course is designed to aid practicing physicians in applying to clinical problems certain concepts relatively recently developed by the physiological sciences concerning the pathogenesis of disease. The effects of therapeutic procedures, particularly as they cast light on the physiological processes under discussion, will also be considered. Registration is limited. Requests for registration should be addressed to Dr. Thomas H. Sternberg, Assistant Dean for Postgraduate Medical Education, University of California Medical Center, Los Angeles 24.

ILLINOIS

Personal.—Dr. Milton A. Dushkin, assistant medical director, North Shore Health Resort, Winnetka, has been appointed psychiatric consultant on the staff of the Illinois State Office of Civil Defense.

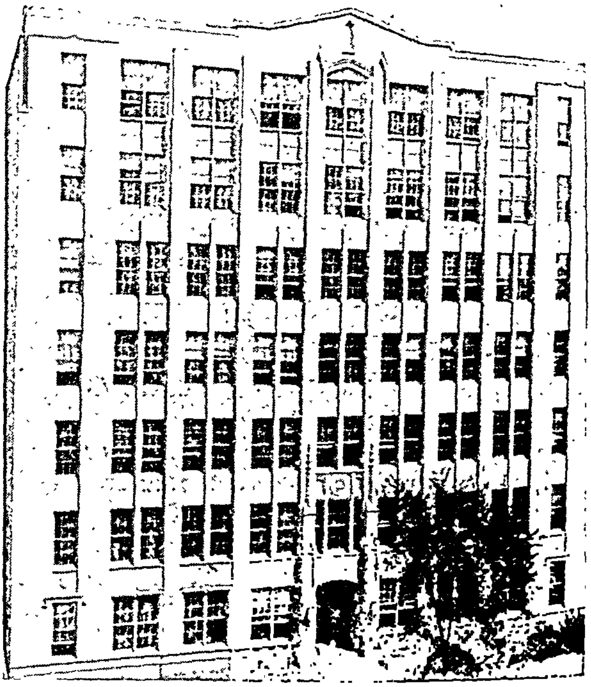
Dr. Peterson Night.—Dr. Martin D. Peterson, Paxton, was honored recently when more than 125 persons attended a banquet in appreciation of his service to Paxton, where he has practiced for 38 years, and to Rankin, which he has served for 9 years. The Paxton Chamber of Commerce presented him with a plaque in commemoration of the event. Dr. Peterson has served as county physician for the past 15 years and city physician for the past 20 years.

Chicago

Volunteer Medical Company.—A meeting of the Volunteer Medical Company 9-20, U. S. Naval Reserve, will be held at the U. S. Veterans Research Hospital, Room A-302, 333 E. Huron St. (MOhawk 4-6600), at 8:15 p. m. Sept. 27. "Urological Complication of Gynecologic Surgery" will be presented by Dr. Alfred W. Kneucker, associate in surgery, Chicago Medical School.

Courses in Radiological Physics.—Courses in two new specialized fields created by the atomic age, health physics and radiological physics, will be offered by the University of Chicago School of Medicine, beginning Oct. 4. Both two year programs lead to the master's degree. The research institutes of the university have a battery of radiation-creating machines ranging from a 450 million volt synchrocyclotron to linear accelerators, betatrons, and other specialized devices. The Argonne Cancer Research Hospital, built on the Midway by the Atomic Energy Commission, and operated for it by the university, is specially designed for the medical use of all radioactive sources in investigation and treatment. The new courses will be given in the department of radiology of the university's medical center, under the supervision of Lester S. Skaggs, associate professor of medical physics. Physicists, biologists, and doctors will participate in the instruction. During the second year of the courses, students will be employed half-time either in the university's health physics service or in the department of radiology.

Research Building Dedicated.—The new seven-story Morton Medical Research Building on the Northwestern University Chicago campus will be dedicated at 10:30 a. m. Sept. 27, during the 98th Founders Day ceremonies commemorating the establishment of the medical school. The building was made possible by a bequest of 2 million dollars, left in his memory by the widow of Mr. Joy Morton. Their son, Sterling Morton, chairman of the board of the Morton Salt Co., will make the presentation speech. Physicians participating in the dedicatory ceremonies will include: J. Roscoe Miller, president of the university, Richard H. Young, dean of the medical school, and Smith Freeman, professor and chairman of biochemistry. The building (310 E. Superior St.) is connected to the Montgomery Ward Memorial Building, which houses the medical and dental schools. Its features include movable metal wall partitions, which can be set up at any 10 ft. interval within the building, allowing speedy conversion of laboratories to almost any size. The department of surgery will conduct its research on the top floor, which is connected with the department of anatomy in the Ward building. On the fifth and sixth floors the departments of pharmacology and obstetrics and gynecology are connected to the department of physiology and bacteriology in the Ward building. On the third and fourth floors of the Morton building is the department of medicine; those floors in the Ward building accommodate, in addition to other sections, the department of biochemistry and some of the Montgomery Ward clinics. On the second floor, opposite other of the Ward clinics, are the departments of radiology, urology, and orthopedic surgery and a special radioisotope laboratory. The first floor of the Morton building has facilities for the department of neurology and psychiatry and for clinical art and photography.



Morton Medical Research Building.

INDIANA

Course in Electrocardiography.—The staff of the Robert M. Moore Heart Clinic of Indianapolis General Hospital will give a course in electrocardiography beginning the first Thursday in October. The course, which will be open to all physicians in Indiana, will be held in the Lilly Auditorium at General Hospital 7:30-9 p. m. Further information may be obtained by writing to the Robert M. Moore Heart Clinic, Indianapolis General Hospital, Indianapolis 7.

Personal.—Dr. Raymond M. Rice, who has been affiliated with Eli Lilly and Company since 1936, has been named executive director of medical research. He has been associate director of research since 1951 and before that was director of the medical

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

division.——Dr. Frank G. Keller, who has practiced in Alexandria since Jan. 6, 1893, retired in July and will divide his time between Grosse Pointe, Mich., and Lexington, Ky., where his children live. All physicians in Alexandria joined other friends at a farewell dinner July 1.——Dr. Leon T. Bogmenko, a graduate of the Imperial University of Saratov, Russia, and a resident of the United States since 1922, has been named medical and clinical director of the Wabash Valley Sanitarium at Lafayette. Dr. Bogmenko has been affiliated with Cook County Hospital, Chicago, the U. S. War Department, and the Veterans Administration and has served as health officer with the army of occupation in Japan.——Dr. William H. Wood became clinical director of the Norways Foundation Hospital, Indianapolis, July 1.

LOUISIANA

Postgraduate Seminar.—The first annual postgraduate seminar, cosponsored by the Third District Medical Society of Louisiana and the Lafayette Parish Medical Society, will be presented at the Evangeline Hotel in Lafayette, Oct. 1, 9:30 a. m. The program includes the following presentations by guest speakers, all of New Orleans:

Philip M. Tiller, Hormones in General Practice.
Morris Shushan, Liver Disease in Ambulatory Patients.
Richard E. Fowler, Congenital Heart Disease.
Daniel W. Hayes, Problems in Control of Diabetes.
Walter R. Akenhead, Gastrointestinal Bleeding.
Charles J. Miangolarra, Treatment of Hyperthyroidism.
Milton L. McCall, Management of Toxemia of Pregnancy.
John Adriani, Nerve Block in Management of Labor.
George T. Mellinger, Recent Advances in Treatment of Prostatic Disease.
Irving Redler, Recent Advances in Treatment of Fractures.

The program will include lectures, a round-table luncheon, medical motion pictures, and scientific exhibits. An invitation is extended to all interested members of the medical profession. There will be no registration fee. For information write Dr. Arthur A. Stamler, Secretary-Treasurer, Third District Medical Society, 510 St. Landry St., Lafayette.

MICHIGAN

Medical Forums.—In cooperation with the *Detroit Free Press* the Wayne County Medical Society will present "Living with Cancer," the last of three medical forums, Sept. 26, 8:15 p. m., at the Rackham Memorial Auditorium, Detroit.

Personal.—Providence Hospital of Detroit has appointed Dr. Robert I. McClaughry, formerly assistant dean of the Wayne University College of Medicine, Detroit, as director of medical education.——Dr. Elwood A. Sharp, Detroit, director of clinical investigation for Parke, Davis & Company since 1929, has been promoted to medical assistant to the firm's president. Dr. Elmore C. Vonder Heide, associate director of the clinical investigation department, has been named successor to Dr. Sharp. Dr. Sharp served 13 years in the Medical Corps of the United States Navy. Dr. Vonder Heide is on the staff at Harper Hospital and also has been an instructor in internal medicine at Wayne University College of Medicine. He is a director of the Michigan Arthritis and Rheumatism Foundation and medical advisor to the Multiple Sclerosis Foundation.

NEBRASKA

Circuit Course.—The Nebraska State Medical Association will present its fifth traveling postgraduate circuit course in Scottsbluff, Sept. 26; North Platte, Sept. 27; Grand Island, Sept. 28; Norfolk, Sept. 29; Fremont, Sept. 30; and Nebraska City, Oct. 1. According to Dr. William E. Wright, Creighton, president of the association, a nationally known group of doctors will speak on heart, cancer, and tuberculosis. Co-sponsors of the series are the Nebraska Heart Association, Nebraska division of the American Cancer Society, and the Nebraska Tuberculosis Association. All meetings will start at 1 p. m., continue until the dinner hour, and conclude with an evening meeting.

NEW JERSEY

Pediatric Amputee Conference.—A Congenital Child Amputee Conference and Clinic will be held Oct. 1 at the Kessler Institute for Rehabilitation, Pleasant Valley Way, West Orange. "Congenital Malformations and General Principles of Rehabilitation of the Congenital Amputee" will be presented at 10 a. m. by Dr. Henry H. Kessler, medical director, Dr. Earl F. Hoerner, clinical director, and staff specialists. Motion picture films and demonstrations will precede the luncheon hour, and clinic and examination of congenital amputee children will follow it. Congenital amputee children may be medically referred for program and examination. The conference is open to doctors, nurses, limb makers, therapists, and other rehabilitation personnel without charge. Advance registration should be made by calling Miss Joyce M. Collins, ORange 3-6571.

NEW YORK

Research Institute Offers Postgraduate Meetings.—The Chronic Disease Research Institute of the University of Buffalo School of Medicine is sponsoring postgraduate educational meetings for physicians of the Buffalo area during the Fall-Winter season. The opening meeting, Sept. 12, was addressed by Dr. Haqvin Malmros, professor of medicine, University of Lund, in Sweden, whose subject was "The Treatment of Hypercholesterolemia." On Sept. 27, Dr. M. F. Oliver, professor of medicine at the Royal Infirmary in Edinburgh, Scotland, will discuss "Coronary Atherogenesis—An Endocrine Problem?" The meetings, conducted in cooperation with the postgraduate education department of the school of medicine and the Western New York State Heart Association, are presented at 8 p. m. at the University of Buffalo School of Medicine.

Annual District Meeting.—The eighth district branch of the Medical Society of the State of New York will hold its 50th annual scientific session and dinner meeting Sept. 28 at Hotel Niagara in Niagara Falls under the presidency of Dr. Sidney L. McLouth, Corfu. The following program will be presented:

Headache, Francis L. McNaughton, Montreal, Canada.
Recent Advances in Vascular Surgery, Jere W. Lord Jr., New York City.
Changing Aspects of Thyroid Disease, Laurence H. Kyle, Washington, D. C.

Addresses will be made at the dinner meeting by Dr. James Greenough, Oneonta, president-elect of the state medical society, and the guest speaker, Charles A. Brady, Buffalo, professor of English at Canisius College, Buffalo, and literary critic of *The Buffalo Evening News,* whose topic will be "The Physician as Seen in Literature."

Symposium—Emergencies in General Practice.—A symposium, "Emergencies in General Practice," will be presented by the Erie County chapter of the New York State Academy of General Practice and Lederle Laboratories of Pearl River, Oct. 1, at the Hotel Statler, Buffalo. Dr. William H. Merrilees, Lancaster, president of the Erie County chapter, has issued a cordial invitation to all members of the medical profession for Erie County. Dr. Theodore H. Noehren, Buffalo, will serve as moderator for the morning session:

Pediatric Emergencies, Edward Press, Chicago.
Plastic Surgical Principles in Farm, Traffic and Industrial Accidents, James B. Brown, St. Louis.
Modern Management of Common Cardiac Emergencies, William G. Leaman, Philadelphia.

Dr. Garra L. Lester of Chautauqua, president, New York State Academy of General Practice, will address the luncheon session, after which the following program will be offered:

Abdominal Emergencies, William R. McCarty, New York City.
Obstetrical and Gynecological Emergencies, Morris E. Davis, Chicago.
Diagnosis and Treatment of Atomic Injuries, Joe W. Howland, Rochester.

The American Academy of General Practice will allow six formal credit hours.

New York City

Management of Mass Casualties.—A symposium on the management of mass casualties will be presented at the New York Academy of Medicine (2 E. 103rd St.) Sept. 27, 7 p. m., by the academy and the U. S. Army Reserve units—1st Army area—with the cooperation of the Office of the Surgeon General, United States Army, and Army Medical Service Graduate School, Walter Reed Army Medical Center, Washington, D. C. The meeting, which will be cosponsored by the New York and

Brooklyn regional committee on trauma of the American College of Surgeons and by the medical schools of Greater New York, is open to the medical profession, public health officers, and civil defense workers. Major Gen. Silas B. Hays, M. C., U. S. Army, surgeon general, will serve as chairman for the following program:

Weapons' Effects and the Anticipated Medical Problems, Lieut. Col. James B. Hartgering, M.C., chief, department of biophysics, Army Medical Service Graduate School, Walter Reed Army Medical Center.
First Aid and Emergency Medical Care, Lieut. Col. Joseph D. Goldstein, M.C., chief, department of atomic casualties studies, Army Medical Service Graduate School, Walter Reed Army Medical Center.
Hospital Organization, Col. Byron L. Steger, M.C., director, Interagency Institutes for Federal Hospital Administrators, Armed Forces Institute of Pathology, Walter Reed Army Medical Center.
Management of Trauma, Col. Joseph R. Shaeffer, M.C., surgical consultant to the surgeon general, Office of the Surgeon General, department of the Army, Washington, D. C.
Psychological Considerations in Nuclear Warfare, Col. Albert J. Glass, M.C., deputy director, neuropsychiatry division, Army Medical Service Graduate School, Walter Reed Army Medical Center.

NORTH CAROLINA

Heart Symposium.—The Winston-Salem Heart Symposium, sponsored by the Heart Association of Winston-Salem and Forsyth County will be held at the Robert E. Lee Hotel, Winston-Salem, Sept. 30, 9 a. m.-9 p. m. Speakers will be Drs. Charles K. Friedberg, New York, Hugh H. Hussey, Washington, D. C., and Arthur J. Merrill, Atlanta, Ga.

Personal.—Dr. J. Lamar Callaway, Durham, recently made a special tour in the Alaskan Theater of Operations for the U. S. Air Force and Army, during which he also made ward rounds, consulted on special dermatological problems, and lectured to medical personnel. Dr. Callaway was recently elected president of the Society for Investigative Dermatology for 1955-56.—— Dr. Watson S. Rankin, Charlotte, trustee of the Duke Endowment, has been awarded the honorary degree of doctor of science by the University of North Carolina, Chapel Hill. Dr. Rankin has served as a member of the House of Delegates of the American Medical Association, a member of the Council on Health and Public Instruction, and Chairman of the Section on Preventive Medicine and Public Health. He has also been secretary and president of the Conference of State and Provincial Health Authorities of North America and president of the American Public Health Association.

OKLAHOMA

Society News.—Dr. Paul C. Williams, associate professor of orthopedic surgery, Southwestern Medical School of the University of Texas, Dallas, will address the Tulsa Academy of General Practice Sept. 26 at Hotel Tulsa on "Chronic Low Back Pain." Reservations for dinner, 6:30 p. m., may be made by calling LUther 2-5904. The program will be at 8 p. m. All physicians are invited.

SOUTH CAROLINA

Practitioners Meet in Columbia.—The South Carolina Academy of General Practice will hold its annual meeting at the Columbia Hotel in Columbia Sept. 27-28. The program includes presentations by Drs. John A. Prior, Columbus, Ohio, and Robert C. Major, Augusta, Ga.; a seminar on prematurity; and a discussion on office anesthesia and analgesia. An invitation is extended to all members of the South Carolina Medical Association.

TENNESSEE

Conferences on Scientific Fairs.—The Oak Ridge Institute of Nuclear Studies, which is conducting work conferences in cooperation with state academies of science, presented the first conference, the Florida Science Fair Work Conference, at the University of Florida, Gainesville, Aug. 25-26. Other conferences scheduled include: Georgia Work Conference on Science Fairs, University of Georgia, Athens, Sept. 30-Oct. 1; Texas Science Fair Work Conference, University of Texas, Austin, Oct. 6-8; West Virginia Science Fair Work Conference, Jackson's Mill, Weston, Oct. 30-Nov. 1; and North Carolina Science Fair Work Conference, North Carolina State Agricultural and Technical College, Greensboro, Nov. 18-19. The conferences are designed to give inspiration and instruction in the total aspects of science fairs as educational tools for the advancement of science. The conferees will be elementary and secondary school teachers, instructional supervisors, educational administrators, and representatives from institutions of higher learning, industry, and communication mediums.

State Association Revises Postgraduate System.—In changing the type of postgraduate instruction it has been offering for 20 years, the Tennessee State Medical Association will substitute a symposium-type program for its circuit rider course, under which a full-time specialist has traveled over the state presenting lectures in a medical specialty. According to Dr. Frank L. Roberts, associate dean of the University of Tennessee College of Medicine, Memphis, chairman of the symposium committee, the new program will be on a two year trial basis. This year, meetings will be held in 10 cities; next year, 30 meetings will be held. A panel of specialists will present programs designed for general practitioners. The new program, which will offer 12 hours of instruction a year, will be presented from 4 to 6 p. m. and from 7 to 9 p. m. In the middle section of Tennessee the program will be on rheumatic fever in four cities, with the first meeting scheduled for Sept. 28 in Shelbyville. In three cities in eastern Tennessee, beginning Oct. 25 at Cleveland, the program will be on jaundice. The program for western Tennessee (traumatic and emergency surgery) will be held in Jackson, Dec. 7, Dyersburg, Dec. 8, and Memphis, Dec. 9.

GENERAL

Campaign Against Mental Illness.—The National Association for Mental Health has received a $50,000 contribution from the Smith, Kline & French Laboratories, Philadelphia, to help launch, in October, a nationwide campaign to mobilize a "citizens' army against mental illness." A staff of field service experts will work with the association's 33 state member associations and 425 local affiliates.

Psychiatrists Meet at Tulsa.—The annual meeting of the Mid-Continent Psychiatric Association at Western Village Hotel, Tulsa, Okla., Sept. 23-25, has as visiting distinguished guest speakers: Drs. Arnold P. Friedman and Harvey J. Tompkins, New York; Dr. Gordon R. Kamman, St. Paul; Dr. Leslie B. Hohman, Durham, N. C.; Dr. E. Vernon Hahn, Indianapolis; Dr. Dexter M. Bullard, Rockville, Md.; Dr. Abe Hauser, Houston, Texas; Drs. Robert A. Schneider, John Gussen, and Stewart Wolf, Oklahoma City; Dr. Louis A. Schwartz, Detroit; and Dr. H. Holland DeJong, Osawatomie, Kan.

Midwest Regional Librarians.—The Midwest Regional Group of the Medical Library Association will hold its annual fall meeting Oct. 15 at Miles Laboratories in Elkhart, Ind. The program will include talks on phases of current medical research by doctors from the Miles Laboratories and from Notre Dame. After luncheon there will be a general session devoted to library problems, with a panel or symposium, "Temporary vs. Commercial Binding in the Small Library" and another, "Compiling and Using a Procedure Manual in Training New Employees." The chairman of the group is Otilia Goode, A. M. A. Library, Chicago.

Tri-State Medical Meeting.—The Tri-State Medical Society will meet Sept. 28-29 at the Grim Hotel, Texarkana, Ark.-Texas. The session will open Wednesday at 9 a. m. with movies from the American College of Surgeons, after which "The Gallbladder Problem" will be presented by Dr. Robert L. Sanders, Memphis, Tenn., president of the Southern Medical Association, and "Pathology of Gallbladder and Liver" by Dr. William R. Mathews, Shreveport, La. Luncheon will be followed by an address, "The Administration's Medical Program," by Robert L. King, executive assistant to the Vice-President of the United States. Dr. John C. Burch, Nashville, Tenn., president of the Southern Surgical Association, will consider "Indications for Hysterectomy" at 2 p. m. and Dr. Joseph W. Kelso, Oklahoma City, "Technique of Hysterectomy" at 3 p. m. The Tri-State Urologic Society, which will hold its meeting at 2 p. m. Wednesday, will have as guest speaker Dr. James H. DeWeerd, Rochester, Minn.

On Thursday morning Dr. Richard V. Ebert, Little Rock, Ark., will present "Advances in Prevention and Treatment of Heart Disease." The sessions will conclude with a clinicopathological conference, 11 a. m., by Dr. Mathews, with clinical discussion by Dr. Ebert. The meeting is approved for credit by the American Academy of General Practice. Skeet shooting is scheduled for either day of the meeting, and entries in the golf tournament may play on either day.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States and its territories and possessions in the weeks ended as indicated:

Vermont-New Hampshire Medical Meeting.—The sixth annual combined meeting of the New Hampshire and Vermont state medical societies will convene at the Mount Washington Hotel, Bretton Woods, N. H., Sept. 29-Oct. 1. The following presentations will be made at the general session, Saturday, 2 p. m.:

Carcinoma of the Lung, Edward D. Churchill, Boston.
Retrolental Fibroplasia, Trygve Gundersen, Boston.
Is X-Ray Pelvimetry Feasible and Necessary for the General Practitioner Who is Doing Obstetrics?, Charles M. McLane, New York.
Use of Blood and Its Derivatives in General Practice, Sam T. Gibson, Washington, D. C.

Saturday morning the section on surgery will hear a paper by Dr. Ralph H. Adams, Wolfeboro, N. H., and a panel discussion, "The Surgery of Trauma," with Dr. Churchill as moderator. The section on internal medicine will have as guest speakers, Dr. William Dameshek, Boston, who will discuss "Bone Marrow Failure" and Dr. Sam T. Gibson, Washington, D. C., who will present "Diagnostic Problems in Anemia." Guest speakers at the eye, ear, nose, and throat meeting will be Dr. Gundersen, who will consider "Unusual Congenital Oculomotor Anomalies," and Dr. LeRoy A. Schall, Boston, whose topic will be "Cancer of the Larynx." Dr. James Townsend, chief medical officer, U. S. VA Center, White River Junction, Vt., will speak before the general practice meeting about "Diabetes: Pitfalls in the Management of 'Difficult' Cases."

Pediatricians Meet in Chicago.—The American Academy of Pediatrics will hold its 24th annual meeting at the Palmer House, Chicago, Oct. 1-6. Saturday and Sunday will be devoted to the presentation of 10 seminars. Twenty-two round-table discussions will be held from Monday afternoon through Wednesday morning. The general sessions will open Monday at 9:30 a. m. with a symposium on juvenile delinquency (Dr. Sherman Little, Buffalo, moderator). Dr. Harold E. Harrison, Baltimore, will serve as moderator for the Thursday morning symposium on endocrinology. Clinical sessions will be held Thursday afternoon at Children's Memorial Hospital; Children's Division, Cook County Hospital; Research and Educational Hospitals, University of Illinois; Bobs Roberts Memorial Hospital for Children, University of Chicago; and Sarah Morris Hospital for Children. Admission will be by ticket only ($1, including bus transportation to and from the hospital). The following alumni meetings and special events have been scheduled:

Monday luncheons—Buffalo Children's Hospital Alumni; Cook County Children's Hospital Alumni Group; Alumni of the Pediatric Department of the University of Cincinnati College of Medicine; Columbus Children's Hospital Alumni; and Alumni of the University of Rochester School of Medicine and Strong Memorial Hospital.

Monday dinners, 6:30 p. m.—Babies Hospital Alumni Association (New York) and Children's Memorial Hospital Alumni Banquet; evening meeting—Duke Pediatric Society.

Tuesday dinner and meeting—Children's Medical Center Alumni Group, Boston.

Thursday dinner—Bobs Roberts Memorial Hospital Alumni.

There will be a welcome hour (courtesy M & R Laboratories) Sunday, 6-7:30 p. m.; breakfast (courtesy Libby's Baby Foods) Tuesday, 7-9 a. m.; and reception and cocktail hour (courtesy Mead Johnson & Company) Wednesday, 6-7:30 p. m., preceding the banquet at 8 p. m.

EXAMINATIONS AND LICENSURE

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 19-21. Sec., Dr. D. G. Gill, State Office Bldg., Montgomery.

Arizona:* *Examination.* Phoenix, Oct. 12-14. *Reciprocity.* Phoenix, Oct. 15. Exec. Sec., Mr. Robert Carpenter, 411 Security Bldg., Phoenix.

Arkansas:* *Examination.* Little Rock, Nov. 10-11. Sec., Dr. Joe Verser, Harrisburg.

MAGAZINE–TELEVISION REPORT

The following list of current medical articles in mass-circulation magazines and forthcoming network television programs on medical subjects is published each week only for the information of readers of The Journal. *Unless specifically stated, the American Medical Association neither approves nor disapproves of the articles and programs reported.*

TELEVISION

Sunday, Sept. 25

NBC-TV, 2 p. m. EDT. "American Inventory" presents "The Days Grow Long," which dramatizes the need for a new attitude on the part of all Americans toward the country's growing number of older people and their problems.

Monday, Sept. 26

NBC-TV, 9 p. m. EDT. "Medic" features the first of two episodes on postpartum psychosis. Titled "And There Was Darkness," the first episode shows a young mother so depressed after the birth of a baby that she asks to be admitted to a mental hospital.

ABC-TV, 9:30 p. m. EDT. "Medical Horizons," presented in cooperation with the American Medical Association, will originate from Kessler Institute, West Orange, N. J. The report will show advanced methods of treating the handicapped individual, with emphasis on a multidisciplined approach.

Wednesday, Sept. 28

NBC-TV, 11:30 a. m. EDT. "Medical and Health News with Howard Whitman," a segment of the "Home" program.

MAGAZINES

Look, Sept. 20 and Oct. 4, 1955

"The Mentally Ill Tell Their Own Story," by Roland Berg

In a two-part article, *Look's* medical editor and a staff photographer report on their visit to St. Elizabeth's Hospital, Washington, D. C., giving in words and pictures an insight on current diagnosis and therapy.

Parade, Sept. 25, 1955

"Polio Report," by Robert Goldman

"Right now there is no reason to defer your child's inoculation with Salk vaccine in hopes of 'something better' tomorrow or next month. As with other immunizing agents, research on polio must continue slowly, painstakingly for perhaps several years. But it may be predicted safely that one day a greatly improved virus, tested and approved, will be ready for release."

Farm Journal, September, 1955

"Your Medical Check-up," by Caroline A. Chandler, M.D.

Every woman needs "regular and complete medical check-ups spaced according to her age and according to the doctor's recommendation. . . . If your doctor doesn't go along with the idea . . . you have the wrong doctor!"

Pageant, October, 1955

"A New Look at Mental Illness," by Lawrence Galton

The author tells of new drugs and new treatments for the mentally ill. Under drugs, he mentions chlorpromazine and reserpine, glutamine for epilepsy, Metrazol and niacin for reducing confusion in older patients, and Miltown for helping "tense and anxious patients." Under treatments, the author reports on trends in treating mental patients outside of institutions in England, Belgium, and the United States.

"Watch Your Next Operation"

A photographic feature that gives a patient's eye view of procedures before and after an operation.

"America Is Catching Spockitis," by David R. Lindsay

A personality sketch of Dr. Benjamin Spock and his family.

Coronet, October, 1955

"Fluoridation: Is It Safe?" by James Rorty

The author says that the "tide seems to be swinging towards the opponents of the (fluoridation) program. . . . They hold that far from being a public health boon of demonstrated safety and value, fluoridation is a dubious and inadequately tested venture into mass medicine. They argue that it is without precedent in public health history to apply such a wholesale program on the basis of such meager investigations of its safety and effectiveness."

"285 Years of Medicine"

Biographical sketches of four elderly medical doctors: 89-year-old Dr. William Vroom, 93-year-old Dr. William L. Warriner, 97-year-old Dr. Maurice J. Lewi, and 101-year-old Dr. Frederick B. Streeter.

DEATHS

Allen, Charles Alexander, Washington, D. C.; Howard University College of Medicine, Washington, 1910; for many years on the staff of the Freedmen's Hospital; died Aug. 14, aged 70, of congestive heart disease.

Brabham, James Charles ⊕ McColl, S. C.; Medical College of South Carolina, Charleston, 1934; engaged for many years in public health work, first in South Carolina and later in Mississippi; died July 18, aged 46.

Burnside, Isaac Marion, Los Angeles; Marion-Sims Beaumont Medical College, St. Louis, 1899; served on the staff of the Hollywood Presbyterian Hospital; died in Burbank July 2, aged 82, of coronary occlusion.

Cavanagh, John Leslie ⊕ Carlsbad, N. M.; University of Toronto Faculty of Medicine, Toronto, Canada, 1923; interned at the Riverdale Isolation Hospital and Hospital for Sick Children in Toronto, and the Lutheran Hospital in Brooklyn; served with the Canadian Expeditionary Force during World War I; died April 10, aged 58, of coronary occlusion.

Corlett, Thomas Gardiner ⊕ Colorado Springs, Colo.; University of Buffalo (N. Y.) School of Medicine, 1890; died in the Glockner Hospital Aug. 13, aged 87.

Culver, George Albert ⊕ Galveston, Texas; University of Texas School of Medicine, Galveston, 1945; interned at the Gorgas Hospital in Ancon, Canal Zone; served as associate professor of anesthesiology at Baylor University College of Medicine in Houston; on the faculty of his alma mater, now known as the University of Texas Medical Branch; on the staff of the John Sealy Hospital and affiliated hospitals; died May 17, aged 33, of coronary thrombosis.

Du Bois, Franklin Thomas ⊕ Liberty, Ind.; University and Bellevue Hospital Medical College, New York City, 1899; veteran of the Spanish-American war; served as county health officer and coroner; died July 2, aged 85, of senility.

Frost, Edward Harold ⊕ Willmar, Minn.; Louisville (Ky.) Medical College, 1899; for a time vice-president of the Minnesota State Medical Association; past-president of the Great Northern Railway Surgeons Association; held a position on the school board for many years; a city health officer and division surgeon of the Great Northern Railroad; at one time county coroner; past-chief of staff of the Rice Memorial Hospital; died June 2, aged 79, of coronary occlusion.

Gates, Arthur Marion ⊕ Ararat, Va.; Medical College of Virginia, Richmond, 1919; member of the Medical Society of Virginia; coroner for Dan River District, Patrick County; died July 4, aged 63, of pulmonary embolism.

Greaves, Horatio Norman, Champaign, Ill.; American Medical Missionary College, Battle Creek, Mich., and Chicago, 1906; Rush Medical College, Chicago, 1907; on the staff of the Burnham City Hospital; died July 31, aged 74.

Henry, Tully Lee, Wilburton, Okla.; College of Physicians and Surgeons, Little Rock, Ark., 1910; died July 27, aged 69, of coronary occlusion.

Hilton, Walter Scott, Tiffin, Ohio; Starling Medical College, Columbus, 1896; died in the Mercy Hospital June 12, aged 90, of carcinoma of the prostate and an injury received in a fall.

Johnson, George Frederick ⊕ Montalvo, Calif.; St. Louis College of Physicians and Surgeons, 1896; first mayor of East Moline, Ill., and served in that position for 14 years; veteran of World War I; died Aug. 6, aged 82, of arteriosclerosis and diabetes mellitus.

Klaptoz, Adalbert ⊕ Chicago; Medizinische Fakultät der Universität, Vienna, Austria, 1910; was frozen to death in a blizzard near Linz, Austria, while mountain climbing Aug. 8, aged 69.

Kretzmer, Eugene ⊕ Worcester, Mass.; Ludwig-Maximilians-Universität Medizinische Fakultät, München, Bavaria, Germany, 1908; served with the German Army during World War I; died in Fairlawn Hospital July 20, aged 72.

Lambert, Joseph S., Chicago; Northwestern University Medical School, Chicago, 1893; on the staff of the Englewood Hospital; died Aug. 8, aged 88, of chronic myocarditis.

McClellan, P. T. ⊕ Vero Beach, Fla.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1910; served as health officer; died in the Indian River Memorial Hospital June 10, aged 78, of aplastic anemia.

Mitchell, William James ⊕ Chicago; Rush Medical College, Chicago, 1903; died in the Woodlawn Hospital July 28, aged 73, of a cerebrovascular accident.

Nuzum, John Weston Jr. ⊕ New Orleans; Northwestern University Medical School, Chicago, 1951; certified by the National Board of Medical Examiners; member of the Illinois State Medical Society; formerly a resident at the Augustana Hospital in Chicago; served as a first lieutenant in the U. S. Air Force; resident at the Charity Hospital of Louisiana, where he interned; died Aug. 15, aged 29.

O'Dea, Patrick John, Sacramento, Pa.; College of Physicians and Surgeons, Baltimore, 1898; an associate member of the American Medical Association; on the staffs of the West Side and Mercy hospitals; died July 14, aged 80, of heart disease.

Petry, Franklin, Lowell, Ind.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1901; died in the Porter Memorial Hospital, Valparaiso, April 3, aged 81, of abdominal cancer.

Pohly, Albert G., New York City; University of the City of New York Medical Department, 1891; member of the Medical Society of the State of New York; for many years physician for the board of education; served on the staffs of the Lenox Hill Hospital and the Mount Sinai Hospital, where he died Aug. 10, aged 85, of adenocarcinoma of the stomach.

Rubbra-Morris, Jean Olive, Billings, Mont.; University of Kansas School of Medicine, Kansas City, 1945; interned at St. Margaret's Hospital in Kansas City, Kan.; formerly a resident at the Kansas City (Mo.) General Hospital, and the Research and Educational Hospitals in Chicago; on the staff of St. Vincent Hospital; died July 4, aged 34.

Scruton, Foster David, Detroit; University of Michigan Medical School, Ann Arbor, 1914; on the staff of the Detroit Memorial Hospital; died in Monterey Park, Calif., June 6, aged 69, of hypertensive cardiovascular disease.

Stern, Nathan ⊕ Indianapolis; Medical College of Indiana, Indianapolis, 1904; served during World War I; on the staff of St. Vincent's Hospital; died July 18, aged 74, of coronary occlusion and arteriosclerosis.

True, MaBelle, Topeka, Kan.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1897; died Aug. 2, aged 83, of a cerebral vascular accident.

Weiner, Samuel Isaac ⊕ Chicago; University of Illinois College of Medicine, Chicago, 1925; on the staff of Mount Sinai Hospital; died July 9, aged 58.

White, James R., Chicago; Meharry Medical College, Nashville, Tenn., 1897; served during World War I, when he received the Croix de Guerre from France; on the staff of the Provident Hospital; died at a resort near Mears, Mich., July 26, aged 84, of coronary occlusion.

Yarian, Norman Carey ⊕ Cleveland; University of Wooster Medical Department, Cleveland, 1896; on the staffs of the Lutheran and Lakewood (Ohio) hospitals; died in Bay Village, Ohio, July 28, aged 84, of uremia.

⊕ Indicates Member of the American Medical Association.

AUSTRIA

Retarded Elimination of Hydrocortisone.—At the June 16 meeting of the Society of Internal Medicine of Vienna, Geyer and Keibl described their observations on the elimination of injected hydrocortisone in healthy persons and in patients with liver disease and showed that the decomposition of this hormone is greatly retarded in liver diseases. Parenchymal diseases of the liver and biliary obstructions showed the same behavior in this respect. The results demonstrate the importance of the liver in the decomposition of the adrenal cortical hormones.

Hepatic Circulation.—At the same meeting Neumayr and Vetter demonstrated once more the clinical value of the nonsurgical method for ascertaining the hepatic circulation in human beings with the aid of colloidal radioactive gold. Investigations on 15 patients in whom the hepatic minute volume was ascertained simultaneously with radioactive gold and bromsulphalein revealed that the radioactive gold method revealed values that were on the average 15.6% lower than those obtained with the bromsulphalein method. An attempt was made to show that the radioactive gold method reveals values that correspond more closely to the actual quantities of blood in the hepatic circulation than do those obtained with bromsulphalein. This is especially true in patients with functional disturbances in the hepatic parenchyma.

Influencing of the Menstrual Cycle.—At the meeting of the Society of Physicians in Vienna on June 17, Dr. V. Grünberger stated that female patients often express the wish for a postponement of their menstrual cycles because of vacation, competitive sports, or polymenorrhea. Sixty women with polymenorrhea and with normal menstrual cycles were treated with estrogens. The treatment of choice was 20 mg. of the synthetic preparation dienestrol (Retalon) on the fourth and sixth days of the cycle. In 70% of the patients with polymenorrhea and in 87% of the women with a normal cycle, the onset of the next period was postponed for an average of six to seven weeks. At any time, the amenorrhea could be brought to an end by giving the patient two 25 mg. doses of progesterone. Successive menstrual cycles did not show any disturbance. In several patients with polymenorrhea, treatment was followed by a regulation of the menstrual cycle. In only one patient, a woman with glandular-cystic hyperplasia, long-continued bleeding occurred.

Functional Urinary Incontinence.—At a meeting of the Austrian Society of Gynecologists and Obstetricians in Vienna in June, Brandstetter and Gritsch reported that variations of the sphincteral power of the bladder depending on phases of the menstrual cycle may be observed in continent as well as in incontinent women with normal menstruation. The sphincteral capacity is measured as the difference in pressure between the bladder at rest and during squeezing of the bladder by contractions of voluntary muscles. In continent women one may find differences in positive pressure only, depending on phases of the menstrual cycle, while in incontinent women an observed negative difference in pressure may be abolished or turned into a positive difference in pressure at the time of the highest estrogen activity, but only in women in whom the negative difference in pressure is not too great. This makes possible the detection of functional urinary incontinence in women by distinguishing a temporary and a permanent incontinence.

BRAZIL

Total Gastrectomy.—In the third volume of *Publicações da Casa de Saude São Miguel* of Rio de Janeiro, Dr. Fernando Paulino and his co-workers reported 20 total gastrectomies performed in the last five years with no operative deaths. In 15 patients the pathological diagnosis was adenocarcinoma of the stomach, in 3 it was scirrhous carcinoma, in one it was lymphosarcoma, and in one squamous cell epithelioma of the esophagus extending into the stomach. In a follow-up of 19 of these patients, 10 had died; of these 3 lived more than one year. After a period of adaptation of three to six months, they enjoyed until their death a relatively normal life, free from pain and without dietary restrictions. Seven patients died within 10 months after operation. In this group the patients suffered from pain, vomiting, and nutritional disturbances. Of the nine patients still living, one had survived the operation for 30 months and another for 16 months. Both lead a normal life, without dietary restrictions. The other seven patients had been operated on for less than 10 months. Although this series is relatively small, the authors believe that, whenever possible, subtotal gastrectomy is the operation of choice, because, as compared with total gastrectomy, it provides a more comfortable postoperative period, even though the lesion recurs later. Total gastrectomy should be reserved for patients in whom a subtotal operation would not permit wide excision of all malignant tissue.

Acute Leukemia.—Two patients with acute leukemia predominantly localized in the kidneys were reported by Dr. Sílvio Jordão and his co-workers in the *Archives of the Hospital Central da Santa* (March 1, 1955). In the hematological study the authors emphasized the presence of immature and undifferentiated cells that cannot be classified in the normal blood series. According to Maffei this cell is a polyblast. It is also called a microhistiocyte, lymphocytoid cell, microhemocytoblast, and micromyeloblast. The authors agree with Carballo and Rohr regarding the value and position of Ferrata's hemohistioblast in the cell differentiation scale. For them only two cells are undoubtedly of value in the hematological picture of acute leukemia: the polyblast and the hemocytoblast. According to a new pathological concept of this disease, sponsored by the authors, the diagnosis is made by the identification of immature elements, regardless of their topographic distribution. Thus, this disease should be considered as a hyperplasia of the reticuloendothelial system, therefore a systemic disease.

ENGLAND

Cancer Research.—The Annual Report of the British Empire Cancer Campaign for 1954 is based on reports from 15 research institutions in this country and from individual workers and research institutions in Canada, Australia, and New Zealand. At the Chester Beatty Institute the whole tar from cigarette smoke and the neutral fraction have been applied to the skin for 18 months in five strains of mice, with a completely negative result to date. This suggests at most that any carcinogenic properties possessed by the tars are mild. In other experiments in which mice have been exposed for long periods to cigarette smoke the induction of lung cancer has not been observed. As this may simply be due to the unsuitability of this particular species, condensates from cigarette smoke and from cigarette paper smoke have also been examined for the presence of carcinogenic hydrocarbons and, in particular, 3:4-benzopyrene. In the case of the smoke condensate from cigarette paper, examination of a large series of fractions has led to the detection of 3:4-benzopyrene by methods based on photographic fluorescence and to its clear confirmation by the use of the Cary spectrophotometer. No estimate of the amount present has so far been made. In Glasgow, experiments to test the carcinogenic action of tar obtained from mechanically smoked cigarettes, administered over prolonged periods by feeding and by direct injection into the lungs of mice, and of tobacco tars produced under conditions as nearly as possible resembling those in ordinary smoking have proved negative. At the London *Hospital*, cigarette tobacco extracts obtained from the butts of naturally smoked cigarettes have also proved inactive in tests for carcinogenic, initiating and promoting, action.

The items in these letters are contributed by regular correspondents in the various foreign countries.

Nitrogen Mustard.—At the Chester Beatty Research Institute, 43 patients have been treated with the aromatic nitrogen mustard-CB 148, including 15 with Hodgkin's disease, 8 with disseminated lymphosarcoma, and 5 with lymphocytic leukemia. The daily oral dose was 0.1 to 0.3 mg. per kilogram of body weight for periods up to four months. Thirteen of the patients with Hodgkin's disease showed some response, but only two derived substantial clinical benefit. Responses of value have also followed treatment in four of five patients with giant follicular lymphoma and in a few of those with lymphocytic leukemia. Side-effects of nitrogen mustard-CB 148 are less than with nitrogen mustard-HN 2 and triethylene melamine. Although this new nitrogen mustard is a powerful bone marrow depressant, serious damage should be avoidable.

At the Westminster Hospital, nitrogen mustard-CB 148 has been used in 39 patients; 24 with Hodgkin's disease, 2 with lymphosarcoma, 3 with lymphocytic leukemia, 2 with granulocytic leukemia, 4 with plasma cell myeloma, and 3 with generalized carcinomatosis. Good temporary palliation has been achieved in many of the patients. Ten patients with advanced Hodgkin's disease and one with chronic lymphocytic leukemia have been treated with actinomycin but with little clinical control of the disease. Nitrogen mustard has been found to be the most useful drug for the control of plasma cell myeloma. Triethylene melamine has on occasion been used as an alternative to nitrogen mustard, but the remissions obtained with it have not been considered superior to those obtained with nitrogen mustard.

Polycythemia Vera.—At the Chester Beatty Institute in the last six years 49 patients with polycythemia vera have been treated with radioactive phosphorus. No side-effects or radiation reactions have been encountered. In 28 patients the phosphorus was given in two doses, at an interval of 6 to 12 weeks, the average dose being 5 mc. followed by 4 mc. Of these patients, 23 responded satisfactorily, 2 have not responded, one has anemia, one has anemia or leukemia, one has died of leukemia, and 2 could not be traced. In 21 patients, the phosphorus was given in a single injection of 4 to 7 mc. Of these, 15 have responded satisfactorily, one is resistant, 3 have died (one from a cerebral accident, one from heart failure, and one from osteosclerosis myelofibrosis), and 2 could not be traced. A review of 64 patients with chronic granulocytic leukemia treated in the last 17 years shows that of 17 treated with irradiation alone, 7 survived 3 years or longer; of 15 treated by chemotherapy, 4 survived 3 years or longer; and, with a combination of irradiation and chemotherapy, 19 of 32 patients survived for this period. All the surviving patients treated by chemotherapy were treated with Myleran, and the results achieved by this drug, particularly in combination with radiotherapy, were as good or better than those achieved by radiotherapy alone.

Adenocarcinoma of Rectum.—At the Department of Radiotherapy at St. Bartholomew's Hospital between 1937 and 1954, 189 patients with adenocarcinoma of the rectum were treated; in 82% the adenocarcinomas were surgically inoperable because of the extent of the disease, and in 18% they were inoperable because of the poor general condition of the patients. The five year survival rate was 5% as compared with the 12 to 15% rate for those undergoing surgery, a figure that includes early cases. The most striking effect of treatment was the relief of symptoms due to the primary growth. This occurred in over 60% of the patients, and in 41% it was not necessary to perform a colostomy.

Intestinal Metaplasia.—At Mount Vernon Hospital, 52 specimens of duodenal ulcer, 28 of gastric ulcer, and 39 of carcinoma, removed at gastrectomy, were examined for the incidence and extent of intestinal metaplasia at the pylorus, lesser curvature, and greater curvature. Areas of intestinal metaplasia were present in 78% of the stomachs examined (in 93% of those removed for carcinoma, in 82% of those removed for gastric ulcer, and in 65% of those removed for duodenal ulcer). Taking the series as a whole, the incidence of intestinal metaplasia at the pylorus was 71%, at the lesser curvature 46%, and at the greater curvature 35%. In the stomachs removed for duodenal ulcer, the pylorus was involved in nearly 60% of cases, whereas the lesser curvature (15%) and the greater curvature (10%) were seldom affected. In gastric ulcer the incidence at the lesser curvature (57%) and at the greater curvature (39%) was relatively higher, and at the pylorus the incidence was 71%. In the stomachs containing carcinoma the incidence of intestinal metaplasia at the pylorus was 87%, at the lesser curvature 79%, and at the greater curvature 67%. As these findings suggested that gastric carcinoma may arise from areas of intestinal metaplasia in the gastric mucosa, a series of 107 primary carcinomas of the stomach were examined. Of these, 35 appeared to arise from an intestinal type of epithelium. This is considered to be a conservative estimate, and it is probable that about half of all gastric carcinomas arise from areas of intestinal metaplasia.

At the same hospital, the Theratron cobalt unit has been used for the treatment of patients since March, 1954. The apparatus has been so designed that the 100-curie source can be rotated in a vertical plane through 360 degrees and can also be moved through an arc normal to the plane of rotation. The authors of the report have been impressed by the fact that it has been possible to deliver presumably adequate doses of a deep-seated lesion without causing severe reactions and without distress to the patient. Despite the advanced nature of many of the lesions that have been treated, primary regression and, in many, complete clinical disappearance has occurred to an extent not previously observed.

Ulcerative Colitis.—At St. Mark's Hospital there are records of 11 patients with cancer following ulcerative colitis, seven cases of which were found by examining colectomy specimens. The specimens made up a consecutive series, unselected in any way, and seven cancers were found in 120 colectomy specimens. The average age of these 120 patients was 42 years. They all had ulcerative colitis and were operated on primarily for this condition, but seven of them were found to be suffering from cancer of the colon. The present position is summarized by saying that any patient in whom severe ulcerative colitis has lasted more than 10 to 15 years has entered a phase of life when intestinal cancer has become a definite risk. The danger of cancer will increase still further with the years. The risk of cancer is not in itself sufficient to justify colectomy in ulcerative colitis if there is no other indication for such radical treatment, but it may sometimes be considered as an additional argument in favor of colectomy in a long-standing case.

Neuroblastoma.—The report from the Hospital for Sick Children, Great Ormond Street, includes a review of the 94 patients with neuroblastoma admitted to the hospital during the past 30 years; 77 presented symptoms during the first 4 years of life, and in one-third of the patients the first manifestation appeared during infancy. In 41 patients the tumors originated in the adrenal and in 24 from the adjacent sympathetic tissue in the abdomen. Metastases had occurred in two-thirds of the children on admission to hospital. Seventy-seven of the 94 patients have died. Death occurred within six months from the onset of symptoms in 75% of these children. The duration of the illness only once exceeded 14 months. In those fatal cases in which therapy was undertaken, no appreciable prolongation of life resulted. In two patients cure appears to have been the result of a spontaneous regression. A follow-up of 20 patients treated by surgery and/or radiotherapy shows that after two to five years 2 of the 5 treated by surgery, 1 of the 11 treated by radiotherapy, and all 4 treated by surgery and radiotherapy are alive. Further details are given of the 17 patients treated with cyanocobalamin. Ten of these children are still alive. The results to date are taken to indicate that vitamin B_{12} has an appreciable effect in nearly 50% of the patients to whom it has been given, although eventual relapse may occur. The therapeutic effects are encouraging in view of the fact that patients were selected for inclusion in this trial only because their disease was not considered amenable to surgery or radiotherapy, most of them already showing evidence of direct or metastatic spread of the neoplastic process by the time treatment was begun. Moreover, several children had been observed for several months before vitamin B_{12} therapy was instituted, with the result that their general condition was poor and some of them died soon after treatment was started. Even when only temporary regression occurred, this has nevertheless been impressive. The standard dose of vitamin B_{12} that is used is 1 mg. on alternate days, and, in patients who respond, this treatment is being maintained over a period of at least two years.

Carcinomas of Bronchus and Breast.—In a series of inoperable cases of carcinoma of the bronchus at Cambridge, it is concluded that intravenous administration of Synkayvite has a small but useful effect as a clinical radiosensitizer in radiotherapy. It appears to be possible to improve the response of some human malignant tumors to radiotherapy by means of chemical radiosensitizers. At Guy's Hospital, 497 patients with fibroadenosis have been followed for variable periods beginning in 1953, and, of these, 18 have developed carcinoma of the breast. Of 181 patients in whom a mass of fibroadenosis has been removed from the breast, 41 have required a further operation. Of 64 patients in whom a mass of adenofibroma of the breast has been removed, 10 have required a further operation. Fifteen patients with carcinoma of the breast that was inoperable when first seen have been able to undergo operation because of irradiation treatment. Seventy-four patients have been treated with large doses of estrogens. With one exception, these were all patients who were postmenopausal and who all had widespread manifestations of the disease in varying sites, both in the skeletal and soft tissue. Of these 74 patients, 7 were unable to take the drug, in 23 there was no response, in 31 there was a moderate response, and in 13 there was an excellent response.

Blood Grouping.—At Whipps Cross Hospital, blood grouping has been investigated in 434 histologically proved cases of malignant disease. The proportions of the various blood groups for malignant disease as a whole do not differ greatly from the controls. If, however, certain types of malignant diseases are placed in arbitrary classes (male genitourinary; female genitourinary; intestinal; respiratory; reticuloendothelial), some variations are seen. Thus, there is a preponderance of group O type blood in male and female patients with genitourinary cancers and of group MN in female patients with genitourinary and reticuloendothelial neoplasms. In female patients with genitourinary cancers, there is an excess of persons who are Rh-positive, and in patients with the four other classes of disease there is an excess of persons who are Rh-negative. The proportion of group B is remarkably constant in all classes. The percentage of blood group substance excretors seems to be raised in male and female patients with genitourinary and respiratory cancers but not in patients with the intestinal or perhaps the reticuloendothelial neoplasms.

Work of the Psychiatric Nurse.—A report on "The Work of the Mental Nurse," published by a joint committee of the Manchester Regional Hospital Board and the University of Manchester, calls attention to the amount of urinary and fecal incontinence in patients in mental hospitals and the apparent absence of attempts at habit training. It is estimated that in nursing time alone each instance of incontinence represents 10 to 20 minutes' extra work. Successful habit training could change the spirit of a ward, as well as saving unnecessary work. Job analysis shows that in most wards there is little requirement for technical nursing of the type required in a general hospital, and it is possible that by reorganization this requirement could be reduced still further. On the other hand, there are many duties specially related to the welfare of the patients, which may be carried out by a qualified nurse, a student nurse, or a nursing assistant according to the staff available in the ward. In general, these duties are well done, but this success is related not to technical qualifications but to the nurse's experience and natural capacity. Thus, psychiatric nursing is now learned largely by doing the job under the supervision of trained personnel and not by formal technical training. It is recommended that the length and content of the training course should be reviewed, with the object of providing courses that are integrally related to the work of mental or mental deficiency hospitals. This does not imply any reduction of standards but may make the course more attractive for those temperamentally suited to psychiatric nursing, because the inter-relation of theory and practice will be more evident and will grow naturally out of the work in the wards. There should be stricter selection of students for training, so that only those will set out on the full course of training who have a reasonable chance of passing. The grade of nursing assistant should be recognized and training for it standardized.

e job of a psychiatric nurse involves (1) basic nursing—the re and attention given to the patient in the interests of his comfort and general well-being and the maintenance of his physical health, (2) technical nursing—the nursing tasks concerned with the treatment of the particular illness, mental or physical, from which the patient is suffering, and (3) supervision—the tasks of teaching patients to be socially and morally conscious, establishing rapport between nurse and patients in order to build up personal esteem, observing special precautions to prevent violent outbursts, and keeping patients from escaping. To discharge all these functions effectively the trained nurse must, in addition to technical capacity, be able to show affection and understanding to the patient, train patients of varying ages and mental years to maintain their own personal hygiene, and establish a sense of security in the management of the ward.

Welfare State.—According to the annual report for 1954 of the Ministry of Pensions and National Insurance, at the end of 1954 the Ministry was paying over 900,000 war pensions; family allowances to nearly 3,250,000 families; and under the National Insurance schemes nearly 4,500,000 retirement pensions, about 500,000 widows' benefits and guardians' allowances, and 115,000 industrial disability pensions. In 1954, new claims for sickness benefits totaled more than 7 million, for unemployment over 2,500,000, and for industrial benefits over 80,000. The combined yearly cost of these and other social benefits paid by the Ministry was nearly 2 billion dollars. The standard weekly rates of unemployment benefit, of sickness benefit, and of the retirement pension at the minimum pension age have now risen to $5.60 a week for a single person and to $9.10 for a married couple. Widows' pensions have gone up to $5.60 a week and widows' allowances (for the first 13 weeks of widowhood) to $7.70 a week. The allowance for the first or only dependent child was increased to $1.60 a week and for each other child to 50 cents a week. Maternity grants have gone up to $28, home confinement grants to $11.20, and maternity allowances to $5.60 a week. Industrial injury benefits have risen to $9.45 a week for a single person and $13 for a married couple. Disability pensions are now $9.45 a week for 100% disability.

Salk Vaccine Trials Canceled.—Dr. G. S. Wilson, director of the Public Health Laboratory Service, announced on July 1 that the Medical Research Council had canceled the proposed trials with the Salk poliomyelitis vaccine in England. According to reports of informants in England, it is difficult to insure that every particle of virus in such a vaccine is killed, and it is difficult to see how any vaccine prepared by Salk's method can be guaranteed to be safe. Partly for this reason, and partly for immunologic reasons, many virologists believe that a vaccine containing a living, attenuated virus such as those used against yellow fever in man and against anthrax, hog cholera, and cattle plague in animals offers greater promise of success than a "killed" virus.

Obstetric Research.—To further the work of the existing obstetric research team in Aberdeen the Medical Research Council has agreed, in collaboration with the University of Aberdeen and the North-Eastern Regional Hospital Board, to form a unit for research in obstetrics under the direction of Prof. Dugald Baird. The unit will continue long-term research into problems of maternity, using a combination of epidemiological, clinical, and laboratory methods of investigation.

FINLAND

Respirator Treatment of Poliomyelitis.—In *Nordisk medicin* for July 14, Dr. Ossi Pettay reported that in 1954 there were 615 cases of paralytic poliomyelitis or 15 per 100,000 population. Seventy-four of these needed treatment in respirators. Five different types of respirator, each of which had its special merits and shortcomings, were used. The *Emerson* rocking-bed respirator proved to be reliable in practice, but because of its height it was difficult to lift very heavy patients into it. Electrically driven devices for aspiration were found to be reliable. All the patients treated in positive pressure respirators underwent early tracheotomy, the merits of which Pettay endorses in spite of the objection that it causes a severe psychic trauma. He found patients to be so alarmed at the prospect of suffocation that they gladly accepted tracheotomy, which was almost always followed by a large dose of scopolamine and morphine. Infections of the urinary tract were observed in nine patients, and there were two in whom the infection due to Proteus vulgaris proved refractory to treatment. Great difficulties were experienced in restoring the normal functions of the colon. The attacks of tachycardia to which about half the patients were subject did not seem to depend on defective ventilation of the lungs. It may have depended on paralysis of the vagus nerve, and it responded well to treatment with dihydroergotamine.

ISRAEL

Family Health Course.—A new course recently introduced at the Hebrew University-Hadassah Medical School places it in the ranks of those progressive medical institutions tending to lay stress on social and environmental factors in clinical medicine. It is a course in family health, a subject at present taught in only a few universities in the world. This course emphasizes the importance of the family in the study of human disease. It is an outgrowth of the increasing realization that physical illness is often associated with psychological and sociologic factors springing from environmental circumstances. The new course would have been impossible without an appropriate "laboratory," which exists at Hadassah's Community Health Center and aims at promoting the health of the community through methods based on this new approach to medical treatment. The staff consists of physicians, nurses, health educators, psychiatric social workers, a statistician, laboratory worker, psychologist, and an anthropologist. In other words, the health center offers preventive, curative, and rehabilitative services for both physical and psychological disorders but at the same time attempts insofar as possible to eliminate the factors that cause those disorders. That means not only clinical treatment on the premises but also (1) home visits by physicians and nurses who give individual guidance in health and hygiene; (2) efforts to straighten out domestic tangles; and (3) work in community groups by the health educators. The health center was inaugurated two years ago as an experiment, and its apparent success led to the setting up of a similar center at Ashkelon by the local council of the labor fund and the Ministry of Health. Hadassah plans to open two more centers, and the government plans to open four.

The course in family health will be compulsory for all fourth, fifth, and sixth year medical students. In a series of introductory lectures by members of the health center staff, an attempt will be made to integrate the study of pathology with clinical practice as related to individual and family health. The first group of fourth year students has completed this stage, and each student will be assigned a family in the center as his special subject of study until the end of the course. From time to time, groups of 10 students will meet with members of the health center staff to discuss the problems encountered in the studies of their assigned families, and at a certain stage all students will be required to spend a period in residence at the center. Although the new course in family health was recently introduced, facilities for postgraduate training have been available for the past year. Those wishing to specialize in family heal h must be prepared to devote a further five years to it after receiving their medical degree. Most of this time must be spent at a health center.

Cooley's Anemia in Oriental Jews.—In a report in the *Bulletin of the Research Council of Israel* (vol. 4, no. 4, March, 1955) Dreyfuss reported that Cooley's anemia has been observed in members of a Bukharian Jewish family and in Oriental, especially Kurdish, children. Diagnostic criteria for Cooley's anemia were a high erythrocyte count in the presence of a relatively low hemoglobin level (one patient had an erythrocyte count of 6,650,000 per cubic millimeter and 12 grams of hemoglobin per 100 cc.), increased resistance of the erythrocytes to hypertonic salt solutions, and the morphological changes typical of Cooley's anemia. A high incidence of Cooley's anemia was noted by the author in members of three families of Oriental Jews, one from Kurdistan, one from Urfa, and one from Nesibin (Kashmili Jews). The latter two towns are in the southeastern corner of Turkey. At least 17, and possibly 20, of the 32 members of the families examined were found to have the disease. Since the three index cases of these three families were admitted to the hospital because of rheumatic heart disease (a diagnosis proved at autopsy in two of them), a search was carried out for evidences of this disease in the other members of these families. Rheumatic heart disease was diagnosed if clinically and roentgenologically demonstrable lesions were present. Eleven, and possibly 13, of the 32 had rheumatic heart disease. Eight, and possibly 10, had both Cooley's anemia and rheumatic heart disease. The appearance of Cooley's anemia is genetically determined and the susceptibility to rheumatic disease is also considered to be so conditioned, but whether anything more than a chance relation exists between these two conditions in the patients so affected in this series is not known.

New Psychiatric Ward Opened.—Israel's first general hospital department of psychiatry was opened at the Hadassah University Hospital in Jerusalem. The department, which was established by the Hebrew University under the leadership of Prof. Milton Rosenbaum of Cincinnati, started with 10 inpatient beds. Diagnostic and treatment clinics for outpatients will be held twice weekly. The department will provide the core of the clinical teaching of psychiatry to students of the Hadassah Medical School, thus permitting the inclusion of this branch of medicine in the regular undergraduate curriculum as well as serving for the postgraduate training of physicians. Closely associated with the department and integrated into its teaching schedule are the Lasker Child Guidance Center of Hadassah, with its visiting director, Dr. George Mohr, of Chicago, and the Keren Nechuth Mental Hospital, under Prof. H. Winnik. The sum of $150,000 was obtained for the new department as a gift from the Julius and Marie Scheider Foundation in the United States through the good offices of Dr. I. S. Wechsler of New York, a member of the Hebrew University's Board of Governors.

New Clinic Opened.—At a typical Bedouin feast in honor of Mr. Yosef Serlin, Minister of Health, on the occasion of the opening of a two-room clinic in Tel El-Milh, a one hour drive from Beersheba, Sheikh Deeb Salim Abu Rhea said, "The State of Israel has invested millions of pounds in making the desert flourish; it has shown its great interest in easing our hard nomadic life and in making my tribe a settled people." The feast was held in a gigantic black tent that hugged the bleached yellow sands of the Negev. Mr. Serlin answered that making the desert flourish is a blessing to Arab, Jew, and the state.

New School of Dentistry.—A delegation of five dentists paid a two weeks visit to the Hebrew University. All of them were from the United States, where they are active in the drive being conducted in that country by the Alpha Omega fraternity to raise funds for the new Hebrew University School of Dentistry. During their stay in Israel, the delegation advised on the organization of the school and gave lectures and practical demonstrations on dental problems.

World Health Organization Regional Poliomyelitis Laboratory.—The virus laboratory of the Hadassah Medical School will serve as the regional poliomyelitis laboratory of the World Health Organization. The Medical School will receive a one time contribution of $2,000 from the World Health Organization for the purpose of acquiring the necessary equipment.

ITALY

Pathogenesis of Acute Rheumatic Fever.—At a meeting of the Medical and Surgical Society of Verona, Professor Severi said that two main alterations are found in patients with acute rheumatic fever: a fibrin-like degeneration and a marked basophilia made of large cells such as those found in myocardial granulomas. The fact that these alterations can always be found in rheumatic granulomas as a sign of impairment of the precapillary arterioles proves that the agent that causes rheumatic fever very likely attacks the arterial walls. In granulomas in which the muscle alterations are more marked, the newly formed basophils are in close contact with the residue of the altered muscular fibers, and this leads to the assumption that many of these elements should be considered of muscular origin. Their importance is, however, not clear, and it is not clear whether they should be interpreted as the expression of regenerative attempts on the part of the muscle fibers or as elements that have macrophagic capacity.

The main problem in the pathogenesis of acute rheumatic fever is to establish whether the inflammatory manifestations that are found in rheumatic patients should be ascribed to the direct action of a living agent or to one or more toxic chemical factors, whatever the origin may be. In other words, it is a matter of establishing whether the pathogenesis is chemotoxic or vitalistic. In support of the chemotoxic pathogenesis are many common theories, such as the toxinic, the enzymatic, and the allergic, but they do not give a satisfactory explanation for the mechanism of onset of the inflammations and their continued presence. On the other hand, the vitalistic pathogenesis cannot be accepted because the presence of a living agent in the rheumatic lesions has not as yet been demonstrated. The streptococcic pathogenesis, which appears to be the most probable, cannot be strongly supported because the mechanism by which the streptococci carry out their rheumatic-fever-inducing action has not been defined.

Professor Severi advanced the hypothesis that the streptococci act after undergoing a variation of the L type. The L-type streptococci, or midget streptococci, may originate after the initial streptococcemia that is secondary to the oropharyngeal inflammations, which precede the rheumatic attack. They may originate in the areas in which the normal streptococci that escaped the blocking and destructive action of the reticuloendothelial system survived and nested.

These variants would slowly cause some microgranulomas, which, because of their particular area of development near the vessels or in the walls of the vessels or near the margins of the cardiac valves, would at some time of their growth open up into the blood stream. The rheumatic attack with the entire complex of associated anatomic and clinical manifestations should, therefore, be ascribed to this sudden emission of L-type streptococci into the blood. The difficulty of cultivating the L-type streptococci and their slight or absent sensitivity to the standard antibiotics would explain why in rheumatic patients the cultures are always negative and antibiotic therapy ineffective.

Foods That Do Not Nourish.—Prof. Michele Mitolo of the University of Bari stated in *Notiziario Sanitario* (13:1 [Feb. 12] 1955) that some natural foods, when introduced into the organism, cause excessive destruction, elimination, or functional inhibition of essential nutritive principles. They are, therefore, antinutritive foods. The antagonistic activity of sodium and potassium is well known. It occurs also in the case of the multiplication of micro-organisms, which is favored by potassium and blocked by sodium. Calcium inhibits diastole and promotes systole to the point that, in high concentration, it results in the arrest of the heart in an exaggerated systole (calcium rigidity); it acts in a sympathomimetic manner, whereas potassium, its antagonist, acts in a parasympathomimetic manner. Manganese and iron act antagonistically in the development of higher plants so that, when the concentration of manganese increases in the plant, this shows the characteristic signs of iron deficiency (chlorosis), whereas, when the iron increases, manifestations of manganese deficiency can be seen. Amino acids also influence each other, and several pairs that are structurally similar are antagonists. Thus there is antithesis between lysine and arginine and between serine and threonine. Antagonism can also be observed in the case of amino acids that are structurally different. For example, amino acetic acid suppresses the action of serine and alanine. The antagonism between invertin and glucose or fructose is well known, as is also the fact that carbohydrates antagonize the action of vitamin B_1. Rancid fats can oxidize and destroy vitamin A, and an excess of fats decreases the antirachitic activity of a food. There are foods whose excess content of one or more vitamins can induce the deficiency of another vitamin and produce signs of hypovitaminosis or avitaminosis. A gradual diminution of ascorbic acid occurs in the organs of a pigeon in which beriberi has been produced by means of an exclusive rice diet. Sometimes the foods may contain enzymes that split some vitamins; the severe symptoms of muscular paralysis that are observed in animals receiving a diet rich in raw fish are due to the enzyme thiominase, which splits thiamine. The antinutritive elements have a certain selectivity of action. For example, Dicumarol behaves like antivitamin K in animals, whereas it is relatively atoxic for most micro-organisms.

Rheumatology Day.—The third rheumatology day was held in Rome on Feb. 12 and 13. It was organized by the rheumatological center of Rome under the direction of Professor Lucherini, who said that the importance of rheumatology is shown by the interest taken in discovering remedies, such as the recent syntheses of steroids with a marked antirheumatic activity that were derived from biliary acids, and by the preparation of a series of halogenated derivatives of cortisone and hydrocortisone. Professor De Sèze of France said the structural deterioration of an intervertebral disk is characterized by alterations of the nucleus pulposus and the annulus fibrosus that surrounds it. In the so-called preclinical stages, the nucleus pulposus dehydrates and becomes fragmented, while the annulus fibrosus presents at first fragmentation of the laminae and later numerous diastases through which fragments of markedly altered nuclear matter pass and reach the anterior and posterior periphery of the disk. In this phase the production of a classic posterior disk hernia may be observed. This should not, therefore, be considered, as it generally is, an autonomous disease but rather the terminal aspect of a pathological process that evolved in time, with or without marked clinical manifestations. Likewise, lumbar or lumbosacral arthrosis represents the final anatomic phase of the structural deterioration of the disk in vast and advanced forms. Various (professional, static, and dystrophic) etiological and pathogenetic factors can be used to explain the structural deterioration of the disk. The habitus of the patient, especially a state of decreased functional activity, and the mechanical aspects of the structural deterioration of the disk are important. The first phase of the degeneration of the disk is characterized by clinical findings of the so-called painful disk insufficiency; the phase during which a nuclear fragment wedges into the annulus fibrosus is characterized by acute lumbago; and the phase of posterior disk hernia is characterized by sciatica with involvement of the disk and radicle. Treatment should be individualized.

Professor Robecchi of Turin stated that the shoulder-hand syndrome should be classified with the dystrophic syndromes. It should be considered with respect to its proximal and distal localization. The former is a typical scapulohumeral periarthritis; the latter presents at first manifestations of painful swelling of the hand and later of rigidity with multiple trophic alterations. The etiological and pathogenic factors are not yet well defined. In some patients a relationship between the syndrome and a myocardial infarct is present. The treatment of this condition also should be individualized.

NEW ZEALAND

Pituitary Changes in Cryptorchism.—At the 14th meeting of the Otago Medical School Research Society in July, Dr. F. Bielschowsky reported (*Proc. Univ. Otago M. School* 33:17, 1955) on the alterations found in the pituitary of rats in which cryptorchism had been surgically induced 12 to 18 months earlier. These changes consist of an extraordinary hypertrophy and hyperplasia of those basophilic cells that secrete the luteinizing, or interstitial cell-stimulating, hormone. The individual cells vary greatly in size and stainability. Some resemble normal interstitial cell-stimulating hormone cells closely; others are larger and more heavily granulated than normal and have an enlarged Golgi apparatus. Exhausted cells with pyknotic nuclei and vacuolated cells are also present. In cryptorchism the diffuse hyperplasia of interstitial cell-stimulating hormone cells, which is also seen in rats with diethylstilbestrol implants, can assume in certain zones a nodular or even adenomatous character. These observations, in conjunction with the fact that so far in four rats with cryptorchism benign tumors of the breast have developed, suggest that an estrogen secreted by the ectopic testes may be a factor in the pathogenesis of the pituitary changes described.

CORRESPONDENCE

SIMPLE TEST FOR DIAGNOSIS OF METASTATIC CARCINOID (ARGENTAFFINOMA)

To the Editor:—An unusual syndrome has been described recently in association with malignant carcinoid of the small intestine and hepatic metastases (Isler, P., and Hedinger, C.: Metastasierendes Dünndarmcarcinoid mit scheren, vorwiegend das rechte Herz betreffenden Klappenfehlern und Pulmonalstenose—ein eigenartiger Symptomenkomplex? *Schweiz. med. Wchnschr.* **83**:4-7 [Jan.] 1953). This syndrome is principally manifested by peculiar cutaneous flushes, chronic diarrhea, respiratory distress, and valvular disease of the heart. Personal experience with five cases of this syndrome within the past few months and the knowledge of several other such cases makes it likely that there are many more such cases as yet undiagnosed. Because of protean clinical manifestations, the "carcinoid syndrome" may mimic a variety of diseases. The cutaneous flushes are characterized by episodic erythema, patchy cyanosis, and blanching and may be confused with other types of vasomotor instability. They were erroneously ascribed to the menopause in one of our patients. A persistent cyanotic appearance may be noted in the absence of decreased arterial oxygen saturation. The intestinal hypermotility simulates that seen in other conditions including dysentery, sprue, and functional gastrointestinal disorders. A prolonged clinical course aids in distinguishing malignant carcinoid from other malignant intestinal lesions. Paroxysmal dyspnea and wheezing are sufficiently prominent in some of the patients to cause confusion with other conditions causing bronchospasm. Valvular disease of the heart, usually pulmonic stenosis and tricuspid regurgitation, is apparently a late development. The hepatomegaly may lead to confusion of this syndrome with primary hepatic disease and, in the presence of valvular heart disease, may be falsely attributed to congestive failure. Thorsen and his co-workers (Malignant Carcinoid of the Small Intestine With Metastases to the Liver, Valvular Disease of the Right Side of the Heart [Pulmonary Stenosis and Tricuspid Regurgitation Without Septal Defects], Peripheral Vasomotor Symptoms, Bronchoconstriction, and an Unusual Type of Cyanosis: A Clinical and Pathologic Syndrome, *Am. Heart J.* **47**:795-817 [June] 1954) suggested that carcinoid tumors might secrete large amounts of 5-hydroxytryptamine (serotonin) that conceivably could induce the manifestations of the syndrome. Using methods developed in our laboratory hyperserotonemia and an elevated urinary excretion of a serotonin metabolite, 5-hydroxyindoleacetic acid (5HIAA), have been demonstrated in patients with this syndrome. The normal 24-hour excretion of 5-HIAA is 2 to 8 mg. In five patients with the carcinoid syndrome, it was 140 to 628 mg. Measurements of urinary 5-HIAA in a variety of clinical conditions indicate that an increased excretion of 5-HIAA is specifically associated with metastatic carcinoid. Because of the large excretion of 5-HIAA in these patients, a direct color assay for this substance can be employed on a small aliquot of urine. This simple test is an adaptation of the quantitative assay and is based on the development of a purple color, specific for 5-hydroxy-indoles, on the addition of 1-nitroso-2-naphthol and nitrous acid.

The reagents are: 1-nitroso-2-naphthol (0.1% in 95% ethanol); nitrous acid (prepare fresh by adding 0.2 ml. of 2.5% sodium nitrite to 5 ml. of 2 *N* sulfuric acid); and ethylene dichloride. The following methods are used: run a normal urine for comparison; pipette into a test tube: 0.2 ml. of urine, 0.8 ml. of water, 0.5 ml. of 1-nitroso-2-naphthol and mix. Add 0.5 ml. of nitrous acid; and mix again. Let stand at room temperature for 10 minutes, then shake with 5 ml. of ethylene dichloride. If turbidity results the tube should be centrifuged. A positive test is indicated by a purple color in the top layer. No purple color will be seen with normal urine, though a slight yellow may be noticed. Assuming an average 24-hour urine volume of 1,000 ml., a purple color will be seen at levels of 5-HIAA excretion as low as 40 mg. per 24 hours. At higher levels the color is more intense and is almost black at levels above 300 mg. per 24 hours. Another substance, *p*-hydroxyacetanilid, reacts similarly but is found in urine only after administration of acetanilid or related drugs. The color formation may be inhibited in conditions resulting in the excretion of huge amounts of keto acids.

Our experience with five cases of the carcinoid syndrome suggests that an elevated urinary excretion of a serotonin metabolite, 5-hydroxyindoleacetic acid, is a constant feature of this condition. The limits of the chemical diagnostic test can only be defined by a study of many such cases. Large amounts of 5-hydroxytryptamine or serotonin have been found (Lembeck, F.: 5-Hydroxytryptamine in a Carcinoid Tumour, Nature, **172**: 910-911 [Nov. 14] 1953. Ratzenhofer, M. and Lembeck, F. Über den Gehalt an 5-Oxytryptamin in Carcinoiden des Darmtraktes, *Ztschr. Krebsforsch.* 60:169-195, 1954) in solitary and metastatic carcinoid tumors, but it is still not known whether all carcinoid tumors produce 5-hydroxyindoles and secrete excess amounts into the blood. If carcinoid tumor is suspected clinically and the qualitative urine test is negative, a quantitative assay should be performed to detect abnormalities of 5-hydroxyindoleacetic acid excretion not revealed by the simple method.

POISONING

To the Editor:—In THE JOURNAL, May 28, 1955, page 335, in an otherwise scholarly and commendable article ("The Gentle Art of Poisoning") the following assertion is made: "An unmilitary race, the Jews, furnished the largest number of those who devoted their talents to this hand maiden of death." This assertion is, however, not supported by historical documentation. As a Hebrew scholar and historian of medicine, I am compelled to assure the readers of THE JOURNAL that no facts are known that might lend support to this view. The epical parts of the Bible often refer to elimination of enemies by assassination, but the "gentle art of poisoning" does not play a role in Biblical reports. In the Middle Ages, during the epidemic of the Black Death, an accusation was raised that the Jews had poisoned the wells. As a consequence many thousands of Jews were slaughtered. Historical research repeatedly revealed the unfoundedness of this accusation. During the Middle Ages many kings, popes, and princes preferred Jewish physicians. Apart from the consideration of professional skill, this preference was based on the conviction of these dignitaries that Jews would not dare to poison them by so-called medical procedures, since they would thereby bring down disaster upon their co-religionists. A Hebrew medical manuscript of the 13th century "Sefer Hayosher" (Book of Righteousness) urges Jewish physicians to excel in the careful medical treatment of gentiles (Friedenwald, H.: Jews and Medicine, Baltimore, Johns Hopkins Press, 1944, pp. 560, 661).

Finally I wish to comment on the second column of the paper, where the second paragraph refers to Hebrew literature. The drug dudaim (misprinted sudaim) in Genesis 30:14, is indeed Mandragora and was used as an aphrodisiac. The "bitter waters," Numbers 5:18, was used as an ordeal on mystic and not on toxicologic grounds. As to witches there is a general reference to them in Exodus 22:17 without any connection with the art of poisoning.

ADVICE PRIOR TO MARRIAGE

To the Editor:—As an obstetrician and a gynecologist, I have a growing interest in better preparation for marriage among young people. Those of us who have long been in practice know of the number of couples who, finding their marriages going on the rocks, come to their doctors for help. If our young people had better instruction on the "facts of life" before they married, we would have fewer problems in marriage. The physician seldom has the two or three hours necessary to counsel premarital couples even if he were skilled in all phases of marriage. The Planned Parenthood Federation of America is one of the few agencies to which a physician can refer his premarital patients for broader education for marriage. Most of the larger cities have a program of education for marriage in conjunction with other Planned Parenthood services. For their addresses, one may write the Planned Parenthood Federation at 501 Madison Ave., New York 22, N. Y. The Roman Catholic church provides its young people with information in its pre-cana conferences. I am familiar with the course conducted by the Planned Parenthood Association in Chicago, at 203 N. Wabash Ave. A four-session course held weekly each month provides engaged and newly-wed couples with salient facts about marriage. Each two-hour session has a leader who discusses the physical, emotional, and spiritual aspects of marriage, as well as interpersonal relationships and money-management. In these sessions there is much give and take. Before the course is finished many questions have been answered and fears allayed. Patients are referred back to their physicians because one of the important features of the Planned Parenthood Association is not to interfere with the physician-patient relationship. The Planned Parenthood groups know they can not do the whole job. They encourage candidates for marriage to have complete physical examinations by their own physicians. They emphasize that the girls getting married should have a careful pelvic examination. Young people often feel that if they have the blood test required by law, that is all that is needed. Planned Parenthood encourages young people to seek the knowledge and understanding that lead to harmonious marriage. Unfortunately, physicians have neither the time nor the knowledge to cover all aspects of marriage. Education for marriage is a comparatively new service offered by Planned Parenthood Associations, and many physicians may not know of its existence. I should like to recommend that they inform prospective brides and grooms that this essential course is available.

THE CADUCEUS

To the Editor:—The introduction of the caduceus as the insignia of the Medical Corps of the U. S. Army is not an error as stated by Dr. James E. Cottrell (*J. A. M. A.* **158**:1308 [Aug. 6] 1955). In a paper entitled "Medical Symbols and Medical Saints" published in Merck Report July, 1949, I stated that the most satisfactory explanation of how the staff of Mercury with its two wings and two serpents was ultimately chosen as the official insignia of the Medical Corps of the U. S. Army is contained in an article that appeared in the *Classical Journal* (vol. 25, 1929-1930) and which states that in 1909 the caduceus was introduced by Col. John R. van Hoff as a result of extensive studies of Babylonian mythology. Colonel Fielding H. Garrison, the well-known medical historian, became van Hoff's chief supporter in the use of the caduceus, especially after the publication of studies on the subject made by A. L. Frothingham in 1916, the results of which were fully set forth at that time in the *American Journal of Archeology*. Frothingham shows that the Greek god, Hermes, was an assimilation of the old Babylonian snake god, the awakener of life and vegetation and the master of the healing art. Hermes was the first to be represented with the caduceus, the first example of which is to be seen on a libation vase of about 3,500 B. C. found at Lagash in Mesopotamia. The snake god, messenger of the supreme goddess, Ishtar, also was the god of the treaties and their sanctity after wars and the god of the envoys designated as such by the caduceus, bringing peace and armistice messages to the fighting armies. They were protected against all harm by this insignia of their neutrality. Thus Colonel van Hoff suggested the use of the caduceus as the official symbol of the Medical Corps to stress the noncombatant status of that branch of the Army.

DISPOSAL OF DRUG SAMPLES

To the Editor:—In The Journal, June 4, 1955, page 424, in the Correspondence section are letters concerning discarding of drug samples. I have found the Society of St. Vincent de Paul to be my salvation. This society will call for and take clothing, furniture, books, magazines, and even bedding. These things are used for such purposes as family relief, vacation equipment for poor children, Christian burial of unclaimed bodies of Catholic faith, care of seamen, visitation of sick in hospitals, and juvenile crime prevention. For some years I have collected samples of drugs and kept them in a carton that, when filled, is picked up by the society. I notify this agency either by telephone or postcard, the latter incidentally being supplied by the society. Apparently some of this material is used in behalf of a hospital that the society conducts. It contains 250 beds and is for children, many of them foundlings. Some children are adopted; the remainder are kept indefinitely. The hospital, St. Vincent's, sorts out that which can be used and burns or disposes of the remainder. I refer to my own experience simply with the thought that other doctors may find similar institutions in their own locations that may be able to use the samples and other material not desired by the physician.

RETIREMENT FOR DOCTORS

To the Editor:—Several months ago, I proposed a plan for retiring doctors that was published in the Correspondence section of The Journal (158:216 [May 21] 1955). The response from many doctors was very encouraging. Some have suggested that the American Medical Association should undertake to promote it. I am informed that it is against the principles of the American Medical Association to assume financial responsibilities for such enterprise. Therefore, it will have to be promoted by the doctors themselves as a private organization. I realize that this is a great undertaking with many responsibilities and will require the help of many men. If all those interested in furthering the project would be kind enough to send me their names and addresses, and if possible, their willingness to take an active interest, we could then arrange a time and place for a meeting, elect officers, and formulate plans for its development.

Oak Park, Ill.

CHLORPROMAZINE DERMATITIS

To the Editor:—Considerable amounts of chlorpromazine are used in this hospital, and there has been one severe case of dermatitis in a nurse who handled this material. Treatment was instituted after the allergy first became apparent, and she returned to work using the recommended precautions of gloves and other routine care. Even this exposure was too much for her, however, and she developed a generalized dermatitis requiring hospitalization and two months' loss of work after being exposed only to the fumes from broken vials of this material. We are now following the practice of relieving any nurse or any attendant following the slightest allergy to this material completely from all further contact.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Rheumatic Fever Activity Determination by Two Correlative Methods. R. K. Skillman, W. Spurrier, I. A. Friedman and S. O. Schwartz. A. M. A. Arch. Int. Med. 96:51-60 (July) 1955 [Chicago].

Skillman and associates show that the principle of the antigen-antibody reaction has been the basis for numerous tests to identify infectious diseases. It has also been shown that erythrocytes that have been coated with an antigen are agglutinated when antiserum prepared from this coating antigen is added. When complement is added to this system, under certain conditions, hemolysis occurs. Because rheumatic fever is associated with tissue reaction to group A beta-hemolytic streptococci, the studies described aimed to determine whether a means of identifying a specific bacterial antigen, or antibodies elicited by it, could be the means of ascertaining rheumatic fever activity. Two methods of determination were employed. In one method, serum of rheumatic fever patients was used as the antibody source; sheep red blood cells, coated with heat-killed group A beta-hemolytic streptococci, which had been isolated from active rheumatic fever patients, were used as the antigen source; complement was added to produce hemolysis. The other method utilized group A beta-hemolytic streptococci antiserum obtained from rabbits as the antibody source; erythrocytes of rheumatic fever patients, exposed to the antigen for coating in vivo, were used in an agglutination test as the antigen source. In most instances the hemolysis method, using patients' serum as the antigen source, was found to be somewhat more sensitive; in both methods, treating erythrocytes with papain was found to enhance the reaction. Control studies of 77 varied patients, including those from whom alpha-hemolytic and beta-hemolytic streptococci were isolated, showed no instances in which other disease processes interfered with either test method. This would indicate an excellent specificity of these tests in active rheumatic fever. Clinical correlations were obtained for 78 rheumatic fever patients, most of whom were tested at intervals of the disease process. The titers in both test methods were elevated within the first few days of the active process in most cases, and they then gradually subsided and disappeared as the process became inactive. The results also indicated an excellent correlation between the test results and the clinical status of the disease, although the height of the titer was not indicative of the severity of the process. The authors conclude that these methods are of practical value in ascertaining activity or quiescence of a rheumatic fever process, as well as in distinguishing rheumatic fever from other disease processes.

Pulmonary Embolism: A Review with Emphasis on Clinical and Electrocardiographic Diagnosis. S. Krause and M. Silverblatt. A. M. A. Arch. Int. Med. 96:19-25 (July) 1955 [Chicago].

The autopsy incidence of pulmonary embolism is much higher than that anticipated by clinical diagnosis. The authors reviewed the cases of pulmonary embolism that occurred at Montefiore Hospital during the past five years. Of 67 records examined, the authors selected 62, because in 5 the data were inadequate. Autopsies were performed in 33 of the cases. Twenty-nine patients recovered. There were 49 medical cases and 13 surgical. Of the 33 autopsied cases (25 medical and 8 surgical), only 9 were correctly diagnosed before death. With regard to the pathological aspects, the authors differentiate two types of pulmonary embolism: (1) massive, fatal pulmonary embolism without pulmonary infarction and (2) pulmonary embolism with pulmonary infarction. In fatal pulmonary embolism without pulmonary infarction, the main stem of the pulmonary artery and the larger branches are blocked by a clot that is twisted, cylindrical or thickened, fragmented or intact, and varying in length from 15 to 30 cm. The cylindrical clots originate in the femoral and external iliac veins. Because death is usually sudden, there is inadequate time for pulmonary infarction and secondary pathological changes to develop. The lungs are only slightly edematous and hyperemic. The right ventricle is usually dilated. Infarction of the lung secondary to pulmonary embolism was observed in 24 of the 33 autopsied patients. Usually the infarct is pyramidal or wedge-shaped, with its base directed pleurally and its apex at the site of vascular occlusion. The very fresh infarctions are not so sharply defined. During the first few days, the infarct is pink and soft. Later the infarcted area becomes progressively firm and dark until organization is completed. A region of fibrinous pleuritis, resulting in fibrous pleural adhesions, often marks the site of a previous pulmonary infarction. Many infarcts apparently disappear, but, if the lung is carefully inflated and diligent search made, small peripheral scars often indicate the site of the old pulmonary infarction. The incidence of signs and symptoms of pulmonary embolism are recorded as follows: apprehension and related mental symptoms were observed in 60, pulmonary infarction in 58, peripheral circulatory collapse in 50, and failure of the right side of the heart in 45 patients. The authors feel that a high index of suspicion is the first prerequisite for diagnosing pulmonary embolism. Physicians should be especially aware of the frequency of pulmonary embolism as a complication of congestive heart failure. Apprehension, anxiety, and their concomitants should be considered "premonitory" symptoms of pulmonary embolism. These warning signs, often confirmed by early electrocardiographic studies, should lead to vigorous prophylactic treatment. The electrocardiogram may be diagnostic or suggestive of pulmonary embolism when physical signs are absent. The authors feel that in the future, with improved techniques, it may often become possible to remove an obstructing embolism from the main pulmonary artery.

The Effect of Corticotropin and Cortisone on Respiratory Function in Bronchial Asthma. T. W. Fyles, J. A. P. Pare and B. Rose. J. Allergy 26:340-358 (July) 1955 [St. Louis].

Eight patients with bronchial asthma were selected at random and were hospitalized for two weeks at the beginning of the study. A complete medical and allergic work-up was done, including skin tests, hemogram, roentgenograms of the chest and sinuses, excretion of urinary steroids, and pulmonary function tests. After a control period during which treatment was limited to providing symptomatic relief, treatment with corticotropin was started. The patients were then discharged and treated with cortisone given orally, returning at frequent intervals for repeat pulmonary function tests. The pulmonary function tests included vital capacity and its subdivisions, maximum breathing capacity, residual volume, and the index of intrapulmonary mixing. Duplicate determinations of the functional residual volume were made and results were not accepted if there was a difference in excess of 3% of the mean values. These results were compared with predicted normal values for each patient. The degree of improvement seen in the pulmonary function of the eight patients was variable but striking; four patients showed normal pulmonary function at the end of the study; three were normal with the exception of an elevated residual volume; and one showed no change. In three patients in whom the residual volume remained elevated, symptoms of asthma were only in-

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1946 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

completely relieved. It was found that there was a rapid improvement in the vital capacity, maximum breathing capacity, and index of intrapulmonary mixing with treatment, but the residual volume required somewhat longer periods of therapy to return to normal. It is believed that the changes in pulmonary function found in bronchial asthma are due to hyperinflation of the lungs occasioned by the bronchospasm encountered in this disease and that, with treatment sufficient to completely remove the bronchospasm, these changes are reversible.

Regressive Gigantic Bullous Pulmonary Emphysema in Tuberculosis of Adults. D. G. Alarcón. Gac. méd. México 85:73-86 (Jan.-Feb.) 1955 (In Spanish) [Mexico, D. F., Mexico].

Formation of gigantic pulmonary air bullae complicating isoniazid therapy, alone or in association with streptomycin and *p*-aminosalicylic acid, may develop in patients with severe forms of pulmonary tuberculosis, frequently bilateral. This complication has the following characteristics. A rapid clinical favorable response and radical clearing of the exudative and caseous pulmonary lesions observed in the roentgenogram follow the treatment. The cavities and potential pulmonary tuberculous lesions that show as dark spots in roentgenograms taken before the treatment are substituted in posttreatment roentgenograms by gigantic and small air bullae respectively. The bullae are delimited from one another by an extremely fine wall. They grow in large numbers and in groups during the stage of total removal of intracavitary material by isoniazid. Later, they diminish in size and many of them disappear. The air passes freely from the bronchi into the bullae. It can be observed in resected specimens of the lung involved by this complication that cavities turned into air bullae are deprived of intracavitary epithelium, which is replaced by a fine layer of connective cells. The pleural space is occluded. A man with a roentgen diagnosis of a severe form of pulmonary tuberculosis with cavitation was given four doses of Friedmann's vaccine and a total dose of 15 gm. of isoniazid, which was taken at irregular intervals for a period of time not precisely stated. A marked temporary improvement was followed by aggravation, during which a large number of air bullae were seen in the roentgenogram. The treatment consisted of streptomycin, isoniazid, and *p*-aminosalicylic acid in daily doses of 1 gm., 300 mg., and 12 gm., respectively, for the period of regression of the air bullae, about three months, in association with vasodilating drugs. After regression of air bullae, the doses of the drugs were diminished and given at longer intervals until clinical and bacteriological cure of the patient was effected. The author believes that formation of air bullae in the lung depends on several combined factors: (1) destruction of an area of the alveolar parenchyma, even if minimal; (2) free passage of air from the bronchi into the cavity or potential lesion by suction of the involved parenchymal area due to diminished expansion of the lung; and (3) perilesional and bronchial vascular spasm elicited by a sympatheticotonic action of isoniazid. Restoration of bronchial and pulmonary circulation favors regression of the air bullae. Prevention consists in giving isoniazid after a preliminary course of treatment with streptomycin and *p*-aminosalicylic acid and in administering vasodilating drugs in the course of isoniazid therapy. In the case reported by the author, the Friedmann's vaccine seems to have elicited a multiple focal necrotic reaction of pulmonary tuberculous tissues that potentiated the local ischemic action of isoniazid with consequent formation of the bullae.

The Diagnosis of Esophageal Carcinoma by Exfoliative Cytology, Including Two Cases of Cardiospasm Associated with Carcinoma of the Esophagus. M. I. Klayman. Ann. Int. Med. 43:33-44 (July) 1955 [Lancaster, Pa.].

Forty patients in whom pathological lesions of the esophagus were suspected underwent cytological examination by lavage with isotonic solution of three chlorides (Ringer's solution) using a Levin tube. Of the 40 patients, 20 had malignant growths, proved histologically in 18 and by surgical exploration in 2. According to roentgenologic findings, 13 of the 20 patients had malignant lesions, in 4 the roentgen diagnosis was doubtful, and in the remaining 3 the roentgen diagnosis was that of a nonmalignant growth. Esophagoscopic examination revealed malignant lesions in 15 of the 20 patients, and biopsy indicated malignant lesions in 12. In 19 of the 20 patients a correct diagnosis of malignancy was made with the aid of cytological examination using Rubin's modification of the Papanicolaou staining procedure. There were no false-positive cytological reports. It would appear from these observations that exfoliative cytology can detect carcinoma of the esophagus accurately and in cases in which radiology and esophagoscopy fail. Case summaries are presented of three of the patients with esophageal carcinoma that demonstrate clearly the contribution of exfoliative cytology in detecting unsuspected malignancy of the esophagus. Two of these three patients, a 55-year-old woman and a 68-year-old man, both of whom had cardiospasm, were treated for years by dilatations. In the case of the woman, the clinical course did not conform with that of most patients with esophageal carcinoma, and exfoliative cytology was the only diagnostic method that identified the malignancy. Although malignancy was suspected clinically in the man, the first objective evidence of its presence was gained by cytology. Exfoliative cytology in addition to radiographic and esophagoscopic examinations for the detection of malignancy should be performed annually and with each exacerbation of symptoms in patients with cardiospasm. The third patient, a 69-year-old man, presented the problem of differential diagnosis of jaundice. In view of the absence of esophageal symptoms and negative roentgenograms, a bile duct carcinoma was considered most likely. It is noteworthy that malignant cells were recovered from an unanticipated carcinoma of the esophagus. Although the patient was asymptomatic, metastases to the mediastinal nodes had developed. Benign lesions of the esophagus were found in 20 of the 40 patients, and all were correctly reported on the basis of cytological examinations.

Partial Eventration of the Right Diaphragm (Congenital Diaphragmatic Herniation of the Liver). A. Vogl and A. Small. Ann. Int. Med. 43:61-82 (July) 1955 [Lancaster, Pa.].

The occurrence of partial eventration of the right diaphragm with herniation of the liver is reported in three men between the ages of 62 and 78 and in three women between the ages of 49 and 63. In five of the six patients the more common type of partial eventration was observed with involvement of the anteromedian part of the right diaphragm. The following characteristic radiological features were found in these five patients. On fluoroscopy a semicircular or semioval, homogeneous, nonpulsating shadow of soft tissue density was seen in the right lung field, arising from the median portion of the diaphragm with a broad base or pedicle. It was situated close to the right cardiac border and filled the cardiophrenic angle. It became more prominent on deep inspiration when the lateral and dorsal portions of the diaphragm moved downward, while the convex segment either remained at the same level or perhaps even moved upward (paradoxical motion). The mass varied in size from that of an orange to that of a grapefruit. Radiographic studies demonstrated the location of the mass, its homogeneous nature, the sharp, convex, occasionally slightly scalloped outlines, and its continuity with the liver shadow. The sixth patient had the less common form of partial eventration in which the central portion of the right diaphragm is involved. The radiological findings were the same as in the other five patients except for the location of the masses atop the dome of the hemidiaphragm. These observations are virtually diagnostic of partial eventration of the right diaphragm with herniation of liver into the diaphragmatic pouch ("superior accessory lobe" of the liver). If unequivocal confirmation of this diagnosis is desired, it may be obtained by intraperitoneal insufflation of 250 to 1,000 cc. of air, which produces separation of the diaphragm and the liver by a translucent zone of gas. Although artificial pneumoperitoneum was carried out in four of the authors' patients, it must not be considered a routine diagnostic procedure for this type of condition, since simple fluoroscopic and radiographic examination will permit a reasonably certain diagnosis in most cases. Partial eventration of the right diaphragm was observed by other workers in adults and in children. The authors' observations corroborated the impression of others that, as a rule, the condition is an incidental finding, entirely innocuous and not the cause of symptoms. It is therefore almost invariably detected during a routine examination or in the course of investigations of symptoms caused by some other disease, such as ovarian carcinoma with widespread metastases or chronic duodenal ulcer in two of the authors' patients. Aplasia of the diaphragmatic muscle in an area derived from the embryonic septum transversum is offered as a possible explanation for the more common type of hernia of the right diaphragm that is known to exist at birth and is found regularly at the same location. The term congenital diaphragmatic herniation of the liver is suggested as most appropriate for the condition.

Medical Treatment and Prognosis of Ulcerative Colitis. A. Fieschi and F. Cuneo. Minerva med. 46:1171-1174 (April 25) 1955 (In Italian) [Turin, Italy].

The causative factor of ulcerative colitis is still unknown, and attempts to reproduce the condition experimentally have failed. Its frequent association during the last years with allergic states and the prompt, though transitory, response to cortisone and corticotropin therapy seem to support the theory of its being a phenomenon of local hypersensitivity of the Schwartzmann type. Because of its unknown etiology, treatment has to be symptomatic and individualized. General treatment includes blood transfusions, which in some instances are extremely useful, and the administration of liver extracts, liver-protecting preparations, amino acids, insulin, and multiple-vitamin preparations. Complete rest in bed and hospitalization are necessary during the acute phase of the disease, and in severe cases the diet should be integrated with the intravenous administration of amino acids and sugars. Antibiotics and sulfonamides should be used with caution, in order not to modify too markedly the normal bacterial flora of the intestine. The therapy should be discontinued only if a true improvement in the number and character of movements and in the general condition is observed. Oral administration of antibiotics may cause severe damage, such as manifestations of hemorrhagic enteritis, and the eventual formation of resistant strains. Clinical improvement has been obtained with cortisone and corticotropin, but it was not accompanied by adequate anatomic modifications, and in most instances the remission was partial and transitory only. In severe cases the administration of corticotropin may cause peritonitis owing to intestinal perforation. Better results have been obtained with sulfonamides. Recently salicylazosulfapyridine (Azulfidine) has proved greatly beneficial in average doses of 1 gm. given orally four to six times daily. In many cases, psychotherapy can be extremely useful, although it has never resulted in complete recovery. Prognosis of the medical treatment of ulcerative colitis depends on the remissions that are obtained. In general, the results are not too encouraging and no particular drug has proved especially beneficial. If a remission is followed by repeated acute and severe relapses, the prognosis is poor, medical treatment should be discontinued, and surgery should be resorted to.

Use of Fructose in Diet and Treatment of Patients with Diabetes Mellitus. R. Klinger and P. Dalle Coste. Minerva med. 46:1389-1392 (May 16) 1955 (In Italian) [Turin, Italy].

The utilization of fructose by patients with diabetes mellitus was studied by (1) administering both fructose and glucose to a group of patients and comparing the blood sugar levels and the urine values of the two substances; (2) adding a certain quantity of fructose to the diet of the patients and administering insulin in fixed doses; (3) substituting carbohydrates of the standard diet with fructose; and (4) resubstituting the fructose, after several days of administration, with carbohydrates. The results indicated that fructose is utilized very rapidly by the patients even after a prolonged administration of large doses of it. However, it is utilized by these patients at a much slower rate than it generally is by healthy persons. It is useful in large amounts if it is given in divided doses in addition to, or as a substitute for, other carbohydrates. It results in weight gain, decrease of the patient's need for insulin, and improvement in his general metabolic condition. Its administration can be a true therapy for patients with conditions secondary to diabetes mellitus (acidosis and renal and myocardial impairment) as well as for those with intercurrent diseases, when diet and drugs are not beneficial. In such instances the intravenous route of administration can be used, because large quantities of sugar can thus be given, provided the rate of administration is checked to avoid reaching the renal threshold too quickly. The results of this series of studies indicated that fructose, which is easy to administer and definitely devoid of dangers, is useful for patients with diabetes mellitus.

Comparative Life Expectancy of Hypertensive Patients with Surgical and Conservative Therapy. K. G. Pfeffer, H. Nieth and H. Schneider. Deutsche med. Wchnschr. 80:956-958 (June 24) 1955 (In German) [Stuttgart, Germany].

The authors compared the length of survival five or more years after operation in 206 hypertensive patients who underwent sympathectomy with that in 306 patients who received conservative treatment, that is, a diet with a restricted salt content, sedatives, and blood-pressure–reducing drugs. As regards the severity of hypertension the following groups were differentiated. Those of group 1a had relatively slight increases in the systolic and diastolic pressures, the eyeground changes were slight, there were no cerebral changes, and the renal function was normal. In those of group 1b the systolic and, particularly, the diastolic pressure showed a more pronounced increase, and there were circulatory disturbances particularly in the eyegrounds and in the brain. Group 2a included the hypotensive patients with arteriosclerotic changes (sclerosis of the central arterial system, with apoplexy, coronary sclerosis, and aortic sclerosis). Group 2b included those with malignant hypertension with or without renal impairment and with progressive functional and organic changes in the arterial system. The late phases of malignant hypertension with renal insufficiency were classified as group 2c. The results of sympathectomy were especially favorable in the early forms of so-called malignant hypertension (group 1b), that is, of 39 who were subjected to sympathectomy, 36 were still alive after five years, whereas, of 56 patients with this form of hypertension who received conservative therapy, only 32 were alive after that period. Similar differences were observed in the more advanced forms of malignant hypertension (group 2b). More than a third of those treated surgically but only about a sixth of those treated with conservative measures survived more than five years. Surgery did not, however, improve the life expectancy of patients with the late forms of malignant hypertension. Sympathectomy produced no improvement in the patients with advanced sclerosis of the vessels. Uremia was the cause of death less often in those who had undergone sympathectomy than in those who had received conservative measures.

Essential Hyperlipaemia. R. A. Joske. M. J. Australia 1:826-831 (June 4) 1955 [Sydney, Australia].

Joske reviews the literature on essential hyperlipemia and presents the clinical features of seven additional patients, one man and six women, whose ages ranged from 30 to 63 years. Five patients had a family history of cardiac disease and one of cholelithiasis. Skin nodules were present in four patients and tendon nodules in one. Four patients had hepatomegaly and one splenomegaly, while five had pancreatitis and two had cholelithiasis. Vascular disease was present in two patients, one of whom developed status anginosus. One patient had probable pituitary lesions and mild diabetes mellitus. All patients had persistent hyperlipemia, although its degree varied greatly. Four patients also had hypercholesteremia. Treatment by a diet of low-fat content did not invariably reduce the blood lipid content. A prolonged course of heparin treatment in one patient with status anginosus affected neither the clinical nor the biochemical findings. Essential hyperlipemia is considered to be a genetically determined anomaly of metabolism, manifested by a family history of vascular disease, pancreaticobiliary disease or diabetes mellitus. The clinical symptoms include xanthomas of skin or tendons, particularly xanthelasma; variable hepatosplenomegaly; pancreatitis; cholelithiasis; atherosclerosis; and diabetes mellitus. Biochemical investigation shows persistent hyperlipemia due to an increase of neutral fats and sometimes of cholesterol and phospholipids. Treatment at present is dietetic and symptomatic, but its efficacy is not certain.

Leptospirosis in Israel: Clinical Forms and Problems of Treatment. K. Marberg. Harefuah **48**:235-240 (June 1) 1955 (In Hebrew, English Abstract,) [Jerusalem-Tel Aviv, Israel].

A study of 196 cases of leptospirosis observed in Israel during the last five years gave the following results: 95% of the cases were caused by Leptospira grippotyphosa and 5% by Lept. canicola. Jaundice appeared in 70% of all cases. This contrasts with the anicteric course of leptospirosis due to Lept. grippotyphosa in Europe. The local disease is therefore more similar to classical Weil's disease. Icterus was present in 45% of the small group of Lept. canicola cases. Renal symptoms were found in 50% of the cases and in one-third the full hepatorenal syndrome appeared. Only a few meningeal cases were observed, among them three cases of primary aseptic meningitis. The disease was not very severe. The single fatal case was due to Lept. canicola. Antibiotic therapy with penicillin, aureomycin, and terramycin did not give clear-cut results, although in certain severe cases terramycin appeared to shorten the febrile period. Patients with severe hepatorenal disturbances require therapy of lower nephron nephrosis.

Case of Favism. N. A. Bolt. Nederl. tijdschr. geneesk. **99**:1651-1655 (June 4) 1955 (In Dutch) [Haarlem, Netherlands].

Bolt presents the history of a 3-year-old boy, whose mother noted one day that he became very quiet, though ordinarily he was lively, that his skin was yellow, and that he became drowsy and fell asleep. He was fed on awakening but he vomited, and his urine was brownish-black. Abdominal pain developed and recurred after another period of sleep. Examination suggested a sudden severe hemolysis. Poisoning, possibly with the insecticide parathion, was thought of, but the clinical picture differed from parathion intoxication. After a transfusion of 300 cc. of blood and other measures, the boy recovered. The true cause of the hemoglobinemia and hemoglobinuria was not ascertained until the author read A. H. Becker's report (*J. A. M. A.* **155**:1158 [July 24] 1954) on the treatment of favism with cortisone. It was then recalled that fava beans (Vicia faba) were among the foods consumed by the child before the onset of his illness and that his symptoms corresponded to those of favism, which is an allergic form of hemolytic anemia caused by contact with the pollen, or by ingestion of the seed, of the fava bean.

SURGERY

Experiences with the Beck Operation for Coronary Artery Disease. M. W. Selman. Dis. Chest **28**:1-20 (July) 1955 [Chicago].

Experiments carried out on dogs provided ample evidence that the Beck 1 operation will protect the heart against death from ventricular fibrillation and will prevent ischemic areas responsible for angina. The Beck 1 operation is a one stage procedure that consists of four steps: (1) partial ligation of the coronary sinus; (2) abrasion of the epicardium and pericardium; (3) application of asbestos powder over the surface of the heart; and (4) approximation of a pedicle of mediastinal fat to the heart. Selman participated in the performance of this operation by Beck on 31 consecutive patients with coronary artery disease. There were no operative or immediate postoperative deaths. Of 32 consecutive patients who underwent this operation and were followed up postoperatively for at least six months, the cardiac status was excellent in 10 who were able to perform full-time work with little or no pain; the cardiac status was good in 12 who were able to perform full-time or part-time work with significant reduction in pain; 6 patients were able to perform more work than before the operation with some diminution of pain; and 4 patients were therapeutic failures. The fact that 87.5% of the patients operated on were improved and 69% had obtained excellent or good results shows the effectiveness of the operation. The number and size of myocardial infarcts after coronary occlusion were significantly reduced in dogs protected by the Beck 1 operation. The Beck operation cannot stop degenerative and occlusive disease in the coronary arteries. The Beck procedure cannot restore degenerated myocardium and is therefore contraindicated in patients in whom destruction of the myocardium from infarcts has resulted in myocardial failure. The occlusive coronary artery disease may be so rapidly progressive that it overtakes the benefit derived from the operation. The Beck operation results in an increase in the intercoronary and extracoronary communication, thereby augmenting the natural tendency of the heart to increase blood supply to the myocardium following coronary occlusion or narrowing. There is ample experimental and clinical evidence to warrant the widespread application of the Beck operation to properly selected patients with coronary artery disease.

Factors Influencing the Late Results of Mitral Valvuloplasty for Mitral Stenosis. L. B. Ellis and D. E. Harken. Ann. Int. Med. **43**:133-142 (July) 1955 [Lancaster, Pa.].

Of 500 patients undergoing mitral valvuloplasty for predominant mitral stenosis without important associated disease, 13 had been classified as group 2 patients who had some impairment of function, usually dyspnea, which was not progressive; 342 were group 3 patients with chronic dyspnea or repeated attacks of acute dyspnea or pulmonary edema; and 145 were group 4 patients most of whom had had chronic congestive failure. Patients who presented a murmur of mitral stenosis but had no significant symptoms were classified as group 1 patients and were not subjected to valvuloplasty. There were 58 operative deaths. The operative mortality in groups 2 and 3 is now less than 3% and appears to be below 1%. It is 20% in group 4. Two patients were lost to follow-up, and 440 were followed up for an average of 22 months. Of the 440 patients, 343 (78%) showed significant and usually persistent improvement. The factors that led to less good results were (1) age over 40; (2) auricular fibrillation; (3) associated aortic valve disease; (4) associated mitral insufficiency of moderate degree or more; (5) a preoperative valve size of more than 1 square centimeter; (6) a postoperative valve size of less than 2.5 square centimeters; and (7) calcification of the mitral valve. Even in the less successful categories the over-all results were still good in most of the patients. Poor late results occurred in direct proportion to the number of adverse factors present. Mitral valvuloplasty appeared to protect against late peripheral embolization, although the incidence of operative emboli was somewhat greater in patients who had had previous emboli than in the group as a whole. Good end-results depend on intelligent and careful selection of patients and on the quality of the valvuloplasty performed by the surgeon.

Pulmonary Resections in the Light of Functional Tests. G. Vargha. Ztschr. Tuberk. **106**:154-161 (No. 3) 1955 (In German) [Leipzig, Germany].

Pulmonary resections produce irreversible changes, and it is essential that as much functioning tissue as possible be preserved. The author surveys the functional factors that must receive attention in pulmonary resections, discussing these factors on the basis of literature reports and of his own observations. He investigated the respiratory capacity before operation, during the postoperative period, and after the respiratory function had become stabilized again. In more than 200 preoperative examinations and in 100 control tests after resections, he found that pneumonectomy reduced the vital capacity by an average of 13% and the maximum breathing capacity by 10%. Lobectomy reduced the vital capacity by 7% but did not alter the maximum breathing capacity. Segmental resection caused on the average an 8% reduction in vital capacity and a 1% reduction in the maximum breathing capacity. The author also found that complications caused a much greater impairment in pulmonary ventilation than is indicated in the average values. When, after ineffective collapse therapy, lobectomy was combined with decortication or when a lobe was resected that contained a residual cavity, then lobectomy produced only a minimal loss in ventilatory capacity, or it even improved ventilation.

Cavernolithiasis. K. Kivikanervo, H. Laitinen and M. Wäre-Niskanen. Ann. chir. et gynaec. Fenniae 44:1-9 (No. 1) 1955 (In English) [Helsinki, Finland].

In the course of radiological examinations carried out at their clinic, the authors discovered three patients whose lungs exhibited sharply outlined opacities of varying sizes and shapes. In two patients the opacity was within a tuberculous cavity, and in the third, the fragment had apparently moved from the cavity into the communicating bronchus and had become wedged there. The authors designate these fragments cavernoliths, a term used by Cooley in 1953. The authors were able to find only one other report on this condition besides Cooley's, that by Nagel and Hoppe in 1954. Cooley believed that cavernoliths are due to the eruption of parenchymal, caseous, and partly calcified foci into a bronchus; a cavity is formed and larger calcified fragments, which do not pass through the bronchus, remain in it. The authors are inclined to think that the formation of cavernoliths can also take place later, as a result of calcification of pus inside an open cavity. It has also been suggested that cavernoliths may simply be Simon's foci remaining within the cavity after the destruction of the surrounding pulmonary parenchyma. The authors feel that one of their cases indicated such a causation. As regards the diagnosis, they found that laminograms provided a good view of the cavernoliths. Their own experience with collapse therapy (thoracoplasty in two cases and pneumothorax in another) convinced them that complications are likely to result. They agree with Cooley that resection is the only therapeutic measure promising satisfactory results.

Surgical Considerations in Pulmonary Coccidioidomycosis: Report of 100 Cases. B. H. Cotton, G. A. Paulsen and J. W. Birsner. Am. J. Surg. 90:101-106 (July) 1955 [New York].

Complications of pulmonary coccidioidomycosis are now a problem throughout the nation. During the second World War and during the Korean War, millions of troops were in endemic areas, and there has been a rapid postwar expansion of populations in endemic areas. The following complications of pulmonary coccidioidomycosis may occur as sequelae of the acute infection: extreme hilar adenopathy, coccidioma, pleural effusion, bronchiectasis, fibrosis, cavitation, and dissemination. One of the authors reviewed 750 cases of pulmonary coccidioidomycosis, nearly all of which were observed during the past decade in Kern County, Calif. Surgical treatment was employed in 100 of the 750 patients. From medical observation on these 100 patients, endoscopic examinations, surgical findings, and reviews of pathological specimens, the authors evolved the following indications for operations: (1) giant cavity; (2) secondarily infected cavity; (3) check-valve cavity; (4) ruptured cavity (pleural effusion, spontaneous pneumothorax, empyema, bronchopleural fistula, nonexpansile lung); (5) coccidioma; and (6) continued or severe hemoptysis. The authors comment on these different indications. Once the acute phase of the disease has passed, the risk of dissemination following surgery is almost negligible. The authors have seen cavities close during the first six month period but never after six months, and so they believe there should be a six month interval between resolution of the acute stage and surgical treatment. Attempts are made to localize the cavity before operation in order to ascertain whether or not localized resection will be possible or whether lobectomy will have to be performed. A bronchogram is always done next, for in many cases bronchiectasis was found associated with the cavity or within the area of infection. After the bronchographic examination, the authors wait six weeks before resorting to surgical treatment, which is carried out in the same manner as for other pulmonary lesions. The diagnosis was always confirmed either before or after the operation by one or more of the following procedures: complement fixation test, sputum examination, culture, animal inoculation, or histological examination. The operation was successful in all but three of the patients. One patient died during the postoperative period, and in two patients further cavities developed, which required second operations. One patient's second cavity was of tuberculous origin. The other patient's was coccidioidal; apparently either a small cavity was missed at the time of surgery or a small coccidioma "shelled out" to become a large cavity. It may prove easier to make a diagnosis of coccidioidomycosis in vivo than by examination of the pathological specimen. The coccidioidal cavity allows recovery of spherules from the sputum during the acute phase of the disease, but it may lose its identity due to superimposed infection by tubercle bacilli or pyogenic organisms. "Masking" of this type may explain pathologists' reports of a "granuloma of unknown etiology." The authors feel that resection for pulmonary coccidioidomycosis may prevent death and is effective in arresting the disease process. The decision to resort to surgery should be based on mechanical considerations, with complete disregard for the etiological agent, Coccidioides immitis. The coccidioidal cavity is, like lung abscess or bronchiectasis, an operable condition.

Pulmonary Histoplasmosis. T. F. Puckett. Am. J. Surg. 90:92-100 (July) 1955 [New York].

Histoplasmosis is a highly infectious mycosis caused by Histoplasma capsulatum and presents a variety of clinical, pathological, and roentgenologic manifestations. The usual route of infection is the respiratory passage giving rise to primary foci within the lungs. Histoplasmosis has a tendency to occur in epidemics following exposure in heavily contaminated areas by groups of persons. There is evidence that a chronic active form of pulmonary histoplasmosis exists that closely mimics pulmonary tuberculosis. Some of these cases may be reinfection histoplasmosis. Chronic pulmonary histoplasmosis is intermediate between uncomplicated primary histoplasmosis and widely disseminated histoplasmosis. It is also the form that appears to be amenable to surgical therapy. The series reviewed consists of 67 patients from which pulmonary tissue, hilar nodes, or both were removed and H. capsulatum identified in the resected material. The disease process seemed to have become stabilized in all these patients and is probably best classified as healed or healing primary histoplasmosis. All patients had a history of residence in endemic areas, and almost half were in the age group 21 to 30 years. Many were admitted to an Army hospital with a diagnosis of "tuberculoma" and others with "coin lesion" of the lung. A presumptive diagnosis of histoplasmosis was made in several patients who were asymptomatic and were positive reactors to intradermal histoplasmin and negative reactors to intradermal coccidioidin and tuberculin. There were 31 patients who were completely asymptomatic and in whom the lesions were found by routine chest roentgenograms taken for reenlistment, annual physical examinations, or in connection with investigation of complaints other than those referable to the pulmonary system; 8 patients complained of malaise, easy fatigue, and weight loss; 8 had blood-streaked sputum; one had two bouts of hemoptysis; 8 had fever associated with symptoms referable to the upper respiratory tract; 10 complained of transient pleural pain; 15 estimated their onset to coincide with a rather mild but prolonged upper respiratory infection; 5 presented the typical symptoms and clinical findings of a middle lobe syndrome; and in 4 patients the lesions were incidental findings in pulmonary tissue removed for the treatment of other conditions. Complement fixation tests were negative in 15 of 30 patients, and the collodion agglutination test was negative in 23 of the same 30 patients. The intralobar location of the lesion was ascertained in 64 of the patients. This author had previously mentioned the difficulties in identifying H. capsulatum in focalized lesions, and on the basis of further studies he emphasizes that organisms cannot be identified in necrotic foci when sections are stained with hematoxylin and eosin. The periodic acid-Schiff stain as modified by Kligman and Mescon has proved to be a most satisfactory procedure. Unfortunately, it is not specific for cytoplasm and it is therefore frequently necessary to use the oil immersion lens for confirmation, as concretions, cellular inclusions, and other artifacts may simulate H. capsulatum. A complete history and the response to intradermal antigens should be known when tissues from granulomatous lesions are examined. Classically, H. capsulatum has been described as an intracellular inhabitant, but that is not the case with organisms found in the central necrotic portions of granulomas. In the older lesions the organisms may assume a somewhat atypical morphology, and attempts to culture them from resected lesions have been disappointing. The author believes that the organisms in the stabilized residual foci are generally nonviable.

Bilateral Resection Therapy in Pulmonary Tuberculosis. J. K. Kraan. Dis. Chest **28**:44-58 (July) 1955 [Chicago].

The author subjected 14 patients with bilateral pulmonary tuberculosis, in whom the disease was confined to at most two segments of each lung, to bilateral resection. The first operation was carried out on the side on which there was the least risk of loss of function. Should a complication arise in the second operation, the danger for the patient would thus be minimal. Surprisingly good results were obtained with bilateral resection in the first six patients, who have resumed their occupations after eight months of postoperative treatment in the sanatorium. These were all young persons between the ages of 21 and 31, who, even though their tuberculosis was only slightly active, were socially incapacitated because of the presence of tubercle bacilli in their sputum, as was revealed by preoperative weekly examinations of their expectoration. It is impossible to say with absolute certainty that they are permanently cured, but this is true for every recovered tuberculous patient. The most important tuberculous foci have been removed, and it is to be expected that, with prolonged after-treatment and a sensible way of living, they have a reasonable chance of gaining the fight against the pathogenic agent with their own defense powers. It was of great importance that the resection was always as selective as possible and that it was always possible to carry out segmental resection except in one patient in whom the whole upper lobe including the lingula had to be removed. This may be the explanation for the slight loss of function that was observed in the author's patients. The total loss of vital capacity and of maximum respiratory minute volume after successful lobectomy is sometimes not much greater than after segmental resection because it is possible that after the latter intervention the spared portions of the lobe participate little in the ventilation and gas exchange. The author believes that, when the expansion of the lung is good, as it was in his patients, these portions are still of significance and the loss of oxygen uptake of the operated lung can be small. Determinations of pulmonary function after uncomplicated bilateral resections in three of the six patients revealed a slight drop of vital capacity varying from 1.4 to 3.6%, while the maximum respiratory minute volume was reduced by 3.1 and 3.6%, respectively, in two of the patients and was increased by 9.1% in one patient. It is this slight loss in pulmonary function that makes the author believe that, in patients with a localized bilateral tuberculous process, resection therapy constitutes the only possibility of obtaining clinical cure with complete restoration of work capacity.

Adrenal Cortical Hyperfunction (Cushing's Disease): Clinical and Biochemical Study: Results of Subtotal Bilateral Adrenalectomy. J. Decourt, E. Baulieu, J. P. Michard and J. Lerner. Presse méd. **63**:951-954 (June 22) 1955 (In French) [Paris, France].

A particularly malignant syndrome of adrenal cortical hyperfunction (Cushing's disease) with early arterial hypertension was seen in a woman aged 29. First clinical signs appeared abruptly five months after termination of a normal pregnancy, her third, at the time of weaning of the infant. A thorough biological study showed slight increase in the 17-ketosteroids, bearing electively on Jayle's C fraction (17-ketosteroids oxygenated in 11); high elevation of the corticoids as measured by different methods (Heard-Sobell, Gornall, Porter-Silber reactions); slight increase in the glycuroconjugated and sulfoconjugated neutral steroids; and normal amounts of estroids. The patient received five sessions of pituitary roentgen irradiation, with no effect. Then the left adrenal gland was removed almost in its entirety, resulting in no clinical improvement but a transient improvement in the hypertension. A month later about half the right gland was removed, with dramatic improvement. Histological examination of the two glands revealed diffuse spongiocytic hyperplasia of the cortex. Several weeks after the second intervention, signs of postoperative adrenal cortical insufficiency appeared, in the form of eczematous eruptions, arthralgia, abdominal pain, and vomiting. These were successfully treated with cortisone. Biological examination four months after operation showed a permanent decrease in the 17-ketosteroids to about 1 mg., subnormal amount of corticoids, and feeble response to the intravenous infusion of corticotropin. Eight months after the operations the patient was seen to be in good health. She had gained in weight; the facies, skin color, and blood pressure were normal; menstruation had reappeared; and psychic balance was restored.

Endoscopic-Transthoracic Approach in Surgical Intervention on Autonomic Nervous System According to Kux. F. Rosenauer. Wien. med. Wchnschr. **105**:524-526 (June 25) 1955 (In German) [Vienna, Austria].

Endoscopic-transthoracic exclusion of the sympathetic and vagus nerves using Kux's technique (*J. A. M. A.* **147**:1076 [Nov. 10] 1951) was carried out by Rosenauer in 300 patients with various disorders such as hyperhidrosis of the hands and the face, essential hypertension, postcholecystectomy syndrome, disturbances of circulation and phantom pain in the upper extremities, causalgia, duodenal ulcer, angina pectoris, and severe spastic constipation. Illustrative cases are reported. Three patients, a stenotypist, a nurse, and a clerk, with severe hyperhidrosis of the hands, obtained dry, warm hands from bilateral division of the upper thoracic sympathetic chain. In two patients, hyperhidrosis of the face of several years' duration subsided completely after division of the sympathetic nerve distal to the stellate ganglion. Bilateral endoscopic division of the thoracic sympathetic chain and of the splanchnic nerves at several points was carried out in a patient with essential hypertension associated with vertigo, headache, and complete loss of sense of taste. Follow-up after two years showed a maximal systolic pressure of 190 mm. Hg as compared with 240 mm. Hg before the operation. The patient had regained his sense of taste, and headache and vertigo did not recur. Of five patients with postcholecystectomy syndrome, two obtained complete freedom from their symptoms as a result of splanchnicotomy on the right side, and the other three were considerably improved. In a 70-year-old farmer, endoscopic division of thoracic sympathetic chain distal to the stellate ganglion, approximately at the level of the second rib, resulted in complete cure of refractory excruciating phantom pain occurring 30 years after amputation of the right upper arm. The author's results obtained with Kux's technique in 53 patients with duodenal ulcer were less satisfactory than those reported by Kux himself. Bilateral division of vagus and of sympathetic fibers is indispensable, but a definite disadvantage of the endoscopic division of these nerves in patients with duodenal ulcer is the fact that surgical intervention is carried out in the pleural space and that one does not know definitely whether the diagnosis of conditions in the abdomen is not erroneous. In very young patients with duodenal ulcer and in those in whom the roentgen findings do not seem to justify resection and who have severe pain refractory to conservative therapy, Kux's technique should be employed and may yield satisfactory results in 55% of the patients. Two patients with highly refractory constipation caused by permanent spasm of the left portion of the colon had regular bowel movements every day or every second day after endoscopic division of the left vagus nerve. It has been possible in many patients to interrupt rapidly, without major surgical intervention, the waves that pass from the autonomic nervous system to the organs, or from the organs through the fibers of the autonomic nervous system to the central nervous system, and for this reason the method becomes indispensable when the autonomic nervous system is considered more and more as the cause of organic diseases.

Congenital Aganglionic Megacolon. H. Axelrod. Am. J. Surg. **90**:18-25 (July) 1955 [New York].

Axelrod reviews the history of investigations on the pathogenesis and treatment of congenital aganglionic megacolon, also known as Hirschsprung's disease. The disease is in the distal, undilated portion of the large intestine, rather than in the dilated portion, which contributes the word megacolon to the designation of the disease. The dilated portion of the intestine, with its greatly increased lumen, thickened wall, and elongation represents the reaction of a normal bowel to a chronic obstruction distal to it. In the narrowed segment distal to the dilated portion of the colon, the ganglions of Auerbach's plexus are absent but nerve fibers are present, which are nonmyelinated and lie where Auerbach's plexus would normally be situated. When the nerve impulse from the proximal, normal portion reaches this part of the bowel, an intense spastic contraction takes place, the lumen of the bowel is greatly contracted, the normal peristaltic wave reaching it is ended, and with it the forward propulsion of the bolus. Feces are packed into the first portion of the narrowed part of the bowel. This part of the fecal stream can move forward only by sufficient push from the propulsive efforts of the bowel orad to it. Meanwhile, though the aganglionic part of the bowel is incapable of peristaltic function, its other functions are not impaired. Water absorption from the feces continues, and as it does the feces become drier and harder. With the feces now backing up into the normal bowel, dilatation of the latter occurs. If the blockage is complete, acute intestinal obstruction results. The diagnosis of congenital aganglionic megacolon is not too difficult. Obstinate constipation becomes apparent at or shortly after birth. These children will have bowel movements so long as enemas are given, but despite the administration of enemas the overwhelming majority of children will appear with a greatly distended abdomen. When acute intestinal obstruction occurs and is complete, laparotomy will be necessary, with the shortest possible procedure consistent with saving the patient's life. This will usually consist of a transverse loop colostomy proximal to the contracted segment. The author describes Swanson's curative operation with Hiatt's modification, which consists of removal of the entire narrowed, distal segment, the transitional area and a variable part of the distal dilated part of the colon. The author presents the histories of two children, a 6-year-old boy and a 2½-year-old girl who were treated by this operation, which illustrate the excellent results that can be achieved by operative correction of this congenital anomaly.

NEUROLOGY & PSYCHIATRY

The Clinical Syndrome of Aneurysm of the Middle Cerebral Artery. K. Frankel and B. J. Alpers. A. M. A. Arch. Neurol. & Psychiat. 74:46-67 (July) 1955 [Chicago].

Aneurysm of the middle cerebral artery has usually been detected at autopsy. The authors analyzed 12 cases of aneurysm of the middle cerebral artery verified at operation or autopsy in order to define the clinical syndrome and to determine the criteria whereby the diagnosis may be established before rupture. They surveyed the literature and located 129 cases, but the records of only 75 were found to be sufficiently complete to warrant inclusion for study. Data on the two groups of patients are analyzed and compared. In the cases reported in the literature the majority of patients were 20 to 50 years of age, whereas in the 12 patients presented here the ages ranged between 30 and 59. Men predominated. In the majority of patients, symptoms were of less than one week's duration, but in some they had been present for from one month to 15 years. The clinical syndrome of aneurysm of the middle cerebral artery prior to rupture is ill-defined. In the series here reported the only symptom of significance prior to rupture consisted of headache of a nonspecific character. This was true also of the cases recorded in the literature. Seizures were recorded in a few instances and transient weakness in others. In the great majority of recorded instances of aneurysm of the middle cerebral artery, the diagnosis has been made after rupture. The onset under these circumstances has usually been with loss of consciousness, often with focal or generalized seizures, and hemiplegia. Neurological examination has usually, but not always, revealed hemiparesis or hemiplegia, at times changes in the fundi, occasionally hemianopsia, and a scattering of other findings. Signs of meningeal irritation were frequent, due to subarachnoid hemorrhage. The spinal fluid usually contained red blood cells or was xanthochromic, and the pressure tended to be elevated. Little information was obtained from radiological studies. It is not possible to indicate a group of symptoms that could be regarded as significant for diagnosis prior to rupture. It is only possible to state that in patients with long-standing, unexplained headache, with occasional seizures and transitory episodes of hemiplegia or aphasia, the possibility of aneurysm of the middle cerebral artery should always be considered and arteriography performed. After rupture it is not always possible to be certain whether the symptoms result from aneurysm, hemorrhage into a tumor, or cerebral hemorrhage of hypertensive origin.

Reserpine in the Treatment of Psychotics with Convulsive Disorders. J. A. Barsa and N. S. Kline. A. M. A. Arch. Neurol. & Psychiat. 74:31-35 (July) 1955 [Chicago].

The value of reserpine, a crystalline alkaloid from the root of Rauwolfia serpentina, in the treatment of disturbed psychotics has been shown in previous studies. Since there was an indication that patients with convulsive disorders did not respond to treatment as well as the others and since at times the incidence of convulsive seizures seemed to be increased, three groups of patients with convulsive disorders were studied. The first group included 11 schizophrenic patients with occasional convulsive seizures, which in all but two of the patients had begun late, that is, between the ages of 25 and 55. The second group included 25 patients whose mental symptoms were believed to be secondary either to epilepsy or to mental deficiency. Convulsive seizures in all of these patients began in early life and occurred more frequently than in the first group. All, with but one exception, required anticonvulsant medication. The third group included seven schizophrenic patients who had undergone various forms of psychosurgery (three, topectomies, and four, prefrontal lobotomies) and who had had convulsive seizures at some time following the operation. None of these patients received anticonvulsant medication at the time of this study. At the onset, reserpine therapy was given orally and intramuscularly, but for maintenance oral therapy was used. It was found that reserpine therapy is not as effective in psychotic patients with convulsive disorders as in psychotics without convulsive seizures. In the former the maximum therapeutic effect to be expected is usually one of sedation. There is an increased incidence of convulsive seizures during the first six weeks of therapy. In treating epileptics with reserpine, it is recommended that therapy be begun with small oral doses and that the dosage be built up gradually. Intramuscular administration of reserpine is not necessary in most cases. Finally, in termination of therapy, the drug should be withdrawn very gradually lest convulsive seizures be precipitated. The question arises as to why the mental symptoms of patients with convulsive disorders did not respond so well to therapy as did those of patients without convulsive seizures. The explanation may be that in the former the mental symptoms, like the seizures, are organically determined and, therefore, not as amenable to drug therapy. Another point to consider is that the paranoid element was usually predominant in the symptomatology of these patients with convulsive disorders, and this symptom is known to be particularly resistant to all forms of therapy.

Peritoneal Shunts in the Treatment of Hydrocephalus and Increased Intracranial Pressure: Four-Year Survey of 62 Patients. I. J. Jackson and S. R. Snodgrass. J. Neurosurg. 12:216-222 (May) 1955 [Springfield, Ill.].

Increased intracranial pressure in patients with hydrocephalus can sometimes be successfully relieved by shunting the excess cerebrospinal fluid from the lumbar subarachnoid space or the ventricles into the peritoneal cavity through a catheter. This method has been used in 62 patients ranging in age from 3 days to 65 years, studied over a period of four years at the University of Texas. A plastic tube with several side vents is introduced either into the right lateral ventricle or the left lumbar subarachnoid space and is fixed in position. Its free end is threaded subcutaneously, either downward on the anterior surface of the trunk for a ventriculoperitoneal shunt or around the trunk to the left lower abdominal quadrant for a lumbar-peritoneal shunt, and the peritoneal cavity is then opened to receive the tube. During the last 18 months, the opening has been made over the liver, instead of lower down, and the tube has been placed over the dome of the liver and fastened to the falciform ligament by a suture. Blocking and kinking of the tube were frequent complications, and in many cases the failure of the tube to function led to a recurrence of the initial symptoms and necessitated reoperation. A second operation was also needed in some of the children because they outgrew the original tube. The total number of operations in these 62 patients, therefore, was 116. One patient was lost to follow-up; 20 died with increased intracranial pressure, although in none of these was the death a direct result of the operation; and 12 others died from various causes, but their intracranial pressure was not increased. Some of the shunts are working and necessary for life; others are now obviously neither working nor necessary, indicating that a temporizing procedure may occasionally tide the patient over until he is able adequately to absorb his excess cerebrospinal fluid. The 29 surviving patients include 22 who are free from increased intracranial pressure and 7 in whom the pressure is now increased in spite of one or more shunting operations. Experience with peritoneal shunts shows that the longer the patients are followed, the poorer the long-term results become; thus only 39% of these patients have received long-term benefit, but, since only two of those with successful shunts are not leading useful or relatively normal lives, the shunting procedure should be regarded as having a certain limited value.

The Use of Hypothermia in Surgical Treatment of Cerebral Vascular Lesions: Preliminary Report. W. M. Lougheed, W. H. Sweet, J. C. White and W. R. Brewster. J. Neurosurg. **12:**240-255 (May) 1955 [Springfield, Ill.].

Experience with two patients subjected to intracranial surgery under hypothermia at the Massachusetts General Hospital in December, 1953, shows that hypothermia protects the brain from anoxia and makes it possible to occlude the cerebral circulation for periods of as much as 14 minutes and 25 seconds without injury. The first patient, a 45-year-old man with a recurrent glioblastoma of the right cerebral hemisphere necessitating hemispherectomy, had an uneventful postoperative course except for tachycardia with pulse rate of 150 beats a minute and electrocardiographic inversion of the T waves in most leads for five or six days. He was alert, mentally oriented, and fully conscious the day after the operation and showed no signs of having suffered cerebral anoxia, although the total time of occlusion of the carotid arteries had been 135 minutes for the right and 45 minutes for the left. He was out of bed on the 50th postoperative day. The second patient, a 17-year-old boy with a large arteriovenous malformation, was also alert and talking on the morning of his first postoperative day. He did well until the morning of the fifth postoperative day, when he went into coma and died. Autopsy showed the right vertebral artery to be thrombosed from the site of its occlusion in the neck up to its junction with the basilar artery. The thrombosis was the result of arterial trauma produced by the occluding bulldog clamp. The clamps chosen for this operation were particularly stiff to insure complete occlusion of the blood supply, and the patient's neck was in such a position during the operation that it was very hard to see the vertebral arteries when applying the clamps; in future, injury to the arteries could probably be avoided by using rubber-shod Poppen clamps. The sum total period of occlusion for all four carotid and vertebral arteries in this patient was 47 minutes and 15 seconds, the longest single period being 14 minutes and 25 seconds. The electrocardiographic and electroencephalographic tracings showed no evidence of anoxia occurring in the heart or brain of either patient during the periods of hypothermia (six and seven hours, respectively) or those of circulatory arrest. Hypothermia is not without risk, but in certain carefully selected cases it may afford the neurosurgeon protection enough to enable him to deal definitively with cerebral vascular lesions.

Chlorpromazine in the Management of Acute Alcoholic States. J. D. Schultz, E. L. Rea, J. F. Fazekas and J. C. Shea. Quart. J. Stud. Alcohol **16:**245-250 (June) 1955 [New Haven, Conn.].

The fact that chlorpromazine produces relaxation, brings about sleep without stupor, reduces agitation, and controls vomiting suggested its usefulness in the management of acute alcoholism. Earlier studies on 64 alcoholic patients were sufficiently encouraging to induce the authors to use the drug in 100 additional patients. The group of 164 patients included 141 men and 23 women. Observations on the earlier series indicated that relatively large amounts of chlorpromazine had to be given. The severity of the physiological disturbance of the patient on admission determined both the dose and the route of administration. The standard dose was 100 mg. of chlorpromazine hydrochloride given intramuscularly on admission, followed by 50 mg. three times daily until symptoms subsided. In severely disturbed patients, 100 mg. of the drug was given intravenously in fluid dilutions, ranging from 10 to 20 cc. of isotonic sodium chloride solution administered in a few minutes to 500 cc. of 5% glucose in water or isotonic sodium chloride solution administered in 30 minutes. In a few of the severely disturbed patients, 150 mg. was given intramuscularly as the initial dose, but 100 mg. given intravenously proved more effective. The subsequent dose in the severely disturbed patient was frequently increased from the standard dose of 50 mg. orally three times daily to 75 or 100 mg. orally for the second or third dose. In a few instances the intramuscular route was used repeatedly. The total dose per patient ranged from 100 to 2,950 mg. over a period of one to six days. Liberal amounts of fluids, usually water and fruit juice, were given by mouth. The authors conclude that chlorpromazine in relatively large doses is extremely helpful in the management of acute alcoholic states. It controls motor excitement, nausea, and vomiting, permits a restful, relaxed sleep, and contributes to the relief of tension and anxiety. The patient retains fluids and nourishment, can be readily aroused for nursing care, and is quickly restored to physiological normalcy. No addiction to chlorpromazine developed, and there were few unpleasant side-effects. Orthostatic hypotension of moderate degree was fairly common at the onset of therapy, and occasionally this hypotension was severe. For this reason the blood pressure of patients given chlorpromazine should be watched closely, particularly when large doses of the drug are administered, and the patients should be kept in a recumbent position.

Chlorpromazine (Thorazine)—Rauwolfia Combination in Neuropsychiatry: Preliminary Report. H. B. Eiber. A. M. A. Arch. Neurol. & Psychiat. **74:**36-39 (July) 1955 [Chicago].

Preliminary testing with the combination of chlorpromazine and Rauwolfia serpentina was begun on 24 patients with such varied neuropsychiatric conditions as schizophrenic reactions, manic-depressive psychosis, senile agitated states, anxiety neuroses, menopausal agitation, epilepsy, primary behavior disorders, and mental deficiency. The subjects were all ambulatory and varied in age from 3 to 92 years. The patients received the combination of 15 mg. of chlorpromazine and 50 mg. of Rauwolfia serpentina (whole root) by mouth. The medicament was given three to four times daily. In some instances the dose was doubled or tripled. In the cases of smaller, younger patients, the dose was halved. No differences were observed when the whole root of Rauwolfia serpentina was replaced by one of its alkaloids, reserpine. The patients were observed first at weekly intervals and later at monthly intervals. There were only three patients who did not improve significantly with this treatment. All the remaining 21 patients showed moderate to marked improvement. It is suggested that this combination may act as a chemical agent on the corticothalamic centers, enabling patients to function at a more satisfactory level. The simultaneous use of the two medicaments appears to be of greater value than when either agent is used singly.

GYNECOLOGY & OBSTETRICS

Chemical Burns of the Vagina. M. J. St. Romain Jr. and F. G. Nix. J. Louisiana M. Soc. **107:**268-272 (July) 1955 [New Orleans].

St. Romain and Nix present observations on 75 women who were treated for chemical burns of the vagina at Charity Hospital, New Orleans, during the period from July, 1949, to July, 1954. A much larger number of chemical burns of the vagina, with less serious complications, were treated on an outpatient basis. The 75 women ranged in age from 17 to 45 years, and parity varied between 0 and 12, with 88% having four or more children. Of these women, 56 admitted using the agents in an attempt to produce abortions. In three instances, tablets were inserted into the vagina in conjunction with intrauterine catheters and vaginal packs by midwives. These three patients, when first seen, showed evidence of pelvic infection. Potassium permanganate was used in 73 of the 75 women; in 52 the tablets were inserted into the vagina as abortifacients; in 21 the tablets or crystals were incompletely dissolved in water in the preparation of douche solutions and the undissolved particles resulted in vaginal burns. One patient used "Orange Blossom suppositories" (containing alum, borax, and petrolatum) to treat a vaginal discharge. Bleeding occurred three days after the insertion of the suppositories, and vaginal examination revealed multiple raw bleeding areas. The remaining woman used tablets of mercuric chloride as an abortifacient. The outstanding symptom of vaginal chemical burns was bleeding. Ulcerative vaginal lesions responsible for the bleeding were present in all patients. The treatment consisted of hemostasis, blood replacement, antibiotics, and antitoxins. Hemostasis was accomplished by sutures in 25 patients. Suturing was impossible in five patients, due to the extensive necrosis, and vaginal packs were used to control the hemorrhage. Transfusion was required in 59 patients; 32 patients received antibiotics. Tetanus and gas gangrene antiserums were administered to 18 patients. The three patients with pelvic infection were treated with nasogastric suction and intravenous fluids in addition to the above forms of treatment. Potassium permanganate is becoming popular among the uneducated and malinformed as an abortifacient, but it is ineffective. Of the 56 women who admitted using the chemical agents as abortifacients, 5 were not pregnant on admission; 6 patients were pregnant but did not return to Charity Hospital for follow-up; and there were 45 cases of proved pregnancies that were followed to termination. These pregnancies resulted in 38 term live births, 2 stillbirths, and 5 abortions. Potassium permanganate used for a cleansing douche may produce serious vaginal burns, if any undissolved crystals come in contact with the vaginal mucosa.

Paracervical Uterine Denervation by Transection of the Cervical Plexus for the Relief of Dysmenorrhea. J. B. Doyle. Am. J. Obst. & Gynec. 70:1-16 (July) 1955 [St. Louis].

Pain synchronous with menstrual bleeding usually referred to as dysmenorrhea occurs in two forms. The pain of primary or essential dysmenorrhea usually occurs during very early menstrual life. It is crampy or colicky in type, localized usually to the low midline hypogastric area, and occurs synchronously with the onset of menstrual flow, although it may precede it for several hours. Its duration is usually several hours to two days. The pain of secondary or acquired dysmenorrhea usually occurs after several years of menstrual life, often not until the second or third decade. It is of a diffuse, dull, aching character and may occur in one or both iliac fossae as well as in the midline. Occasionally, the pain radiates to the lower sacrum or to the medial and posterior thigh or into the vagina. Many young women with primary dysmenorrhea are assured that marriage and childbearing will relieve the condition. Unfortunately, this does not always happen. Of the numerous theories regarding the cause of dysmenorrhea, the most generally accepted is that the discomfort arises chiefly from hypercontractility of the uterine musculature due to an imbalance of its regulators, estrogen and progesterone. Most gynecologists agree that most patients with primary dysmenorrhea will respond to sedation, rest, hygiene, and production of anovulation either by estrogens or testosterone. These remedies are less satisfactory for the acquired type of dysmenorrhea. Temporary relief can usually, but not always, be obtained by prolonged dilatation of the cervical canal. The relative inadequacy of the presacral neurectomy procedure in the relief of both primary and secondary dysmenorrhea is well known, and it has been virtually abandoned for patients with acquired dysmenorrhea at many clinics. Many European gynecologists relieve uterine pain by transection of the intersacral ligaments. The author mentions various denervation procedures and describes his own experience with the transection of the cervical division of the Lee-Frankenhäuser uterovaginal plexus lying in, around, and under the terminal 2.5 cm. of the uterosacral ligaments. It permits sensory denervation of the cervix and fundus of the uterus and the proximal segment of the tubes. The procedure may be done during laparotomy or culdotomy. Since the culdotomy approach is the first step of a vaginal hysterectomy, gynecologists may prefer the vaginal approach particularly if the illumination is improved by the use of the pelviscope set, which consists of a lighted right-angle retractor with twin lights at its tip and a set of two telescopes offering right angle or 45° angle fields of vision with a threefold magnification. The general surgeon may prefer the abdominal approach. It has been the author's practice to reserve the vaginal approach for those patients with dysmenorrhea in whom pelvic examination, both vaginally and rectally, revealed tenderness but no nodulation in the uterosacral ligaments and a cul-de-sac free of induration or masses. The vagina must be free of infection. In the series of 73 cases reviewed in this paper the denervation was done by the vaginal route in 36 cases and by the abdominal route in 37 cases. Neuromuscular and neurovascular autonomic imbalance is avoided with this technique of uterine denervation since both sympathetic and parasympathetic pathways are interrupted. Relief of acquired dysmenorrhea with or without antecedent primary dysmenorrhea was obtained in 69 of 73 cases. The relief was complete in 63 cases. There was no interference with the function of the bladder or rectum. The regrowth of the nerves is prevented by the interposition of the posterior parametrial peritoneum between the transected uterosacral ligaments and the top of the vagina.

PEDIATRICS

Experiences with 180 Cases of Tetralogy of Fallot in Infants and Children. R. D. Rowe, P. Vlad and J. D. Keith. Canad. M. A. J. 73:23-30 (July 1) 1955 [Toronto, Canada].

Advances in diagnostic technique during the last 10 years have opened the way to the correct diagnosis of the tetralogy of Fallot in small infants and children with cyanotic heart disease. Congestive heart failure never occurs during childhood in the natural course of this malformation; consequently, the finding of an enlarged liver with gallop rhythm in a cyanotic child before surgical intervention excludes a diagnosis of tetralogy of Fallot. Some of the more serious cardiac malformations found in infants may have closely similar physical signs, radiological picture, and electrocardiographic alterations, and this often makes differential diagnosis difficult. Early determination of the correct diagnosis, however, is important from a prognostic point of view and full advantage should be taken of such accessory procedures as chest radiography, electrocardiography, ear oximetry, cardiac catheterization, and angiocardiography. Anoxia is the chief cause of death in children with this condition. Those who survive the dangerous first two years show a certain amount of adaptation to anoxia; they are aware of their limitations and often employ maneuvers such as squatting or lying on one side to relieve discomfort or dyspnea. The average age of survival, however, is only 12 years and very few patients survive the second decade. The records of the 180 patients with the tetralogy of Fallot seen at the Hospital for Sick Children, Toronto, show that, of the 40 who died, 67% were less than 2 years old and 83% were less than 5. Medical treatment should be used whenever possible to carry the patient through infancy until he reaches an age at which surgical correction of the defect can be carried out with greater safety. The best age seems to be between 4 and 5. Cyanosis is strikingly lessened in patients who have been operated on successfully, and their exercise tolerance is greatly improved. The purpose of the surgical treatment is to increase the pulmonary blood flow and, while it is not possible now to say how long the improvement will last, the benefit still being enjoyed by patients who were operated on as much as 10 years ago augurs well for their future.

Blood Formation in Infancy: Part IV—The Early Anaemia of Prematurity. D. Gairdner, J. Marks and J. D. Roscoe. Arch. Dis. Childhood 30:203-211 (June) 1955 [London, England].

In premature infants the postnatal fall in hemoglobin level tends to be exaggerated, so that these infants, although starting life with a cord hemoglobin as high as that of normal infants, often develop abnormally low hemoglobin levels during the second month. Usually this early anemia of prematurity slowly improves after about age 4 months but is frequently followed by a second phase of anemia. This late anemia of prematurity does not differ from the hypochromic anemia common in other infants of over 6 months. It reflects the precarious iron balance during infancy, exaggerated by several factors that bear on the premature infant, such as its smaller initial iron stores, its more rapid growth, and its tendency to receive a purely milk diet for a prolonged period. The cause of the early anemia of prematurity has, however, never been understood. Three different mechanisms have been suggested: (1) that the anemia results from abnormally high rate of destruction of red blood cells; (2) that it is the result of the rapidity of body growth outstripping a normal erythropoietic capacity; and (3) that it is the result of a functional immaturity of the bone marrow, a dyshemopoiesis. Each of these three suggested mechanisms was examined by the authors in the light of data obtained in 31 infants having birth weights below 1,620 gm. (3 lb. 9 oz.). The main study concerns a group of 26 infants, to half of whom additional iron was given, while another 5 infants received cobalt as well as iron. The authors found that the early anemia of premature infants is due mainly to the slow response of erythropoiesis to the stimulus of anemia. This slow response is not peculiar to premature infants, but in them its consequence is exaggerated by the rapidity of their growth. Rapid growth also has the effect of prolonging the anemia once it has developed. There is no evidence that an abnormal rate of red blood cell destruction, if it occurs, contributes significantly to the production of anemia. Marrow studies reveal no differences between the myelograms of premature and normal infants. Iron, if given from about the third week, mitigates the anemia but does not always prevent it. Iron is well tolerated and there seems good reason to give it to the smaller premature infants from about the third or fourth week. If cobalt is given in addition to prophylactic iron, a striking increase in erythropoiesis can be provoked, sufficient in most cases to prevent anemia. However, the effects that cobalt may have upon the thyroid make it unjustifiable to administer it routinely to premature infants.

The Schönlein-Henoch Syndrome (Anaphylactoid Purpura) Compared with Certain Features of Nephritis and Rheumatism. I. C. Lewis. Arch. Dis. Childhood 30:212-216 (June) 1955 [London, England].

Similarities between acute rheumatism, acute nephritis, and anaphylactoid purpura, also known as the Schönlein-Henoch syndrome, had been pointed out by Gairdner in 1948 who had also called attention to the fact that an upper respiratory tract infection associated with hemolytic streptococci preceded these conditions so commonly as to suggest bacterial hypersensitivity as an etiological factor. The present report enlarges upon some of the points raised by Gairdner. It is based on 139 cases of anaphylactoid purpura (Schönlein-Henoch syndrome), 297 cases of nephritis, and 307 cases of rheumatism. All of the children with anaphylactoid purpura (Schönlein-Henoch syndrome) had the characteristic exanthem and joint and/or abdominal symptoms. The children with this syndrome, those with acute hemorrhagic glomerulonephritis, and those with acute rheumatism were compared with regard to sex ratio, age of onset, seasonal trends, and the incidence of previous upper respiratory tract infections, particularly those associated with hemolytic streptococci. The authors feel that the evidence they obtained supports a close relationship between anaphylactoid purpura (Schönlein-Henoch syndrome) and acute nephritis, and a bacterial hypersensitivity as a major causal factor in all three conditions. The sharp rise in the numbers of cases of anaphylactoid purpura (Schönlein-Henoch syndrome) in the spring and autumn also suggests a relationship with respiratory tract infections.

THERAPEUTICS

Coronary Dilator Activity and Therapeutic Importance of a Synthetic Drug with a Kellinic Action: the 2-Phenylchromone. V. Ferrari and G. Finardi. Minerva med. 46:1175-1180 (April 25) 1955 (In Italian) [Turin, Italy].

The effects of prolonged administration of 2-phenylchromone (Cromarile), a preparation whose activity, according to some authors, is two times greater than that of kellin, were studied in nine patients with coronary insufficiency. Doses ranging from 45 to 120 mg. daily never caused untoward reactions, and the beneficial effect of the drug was evident from the clinical, electrocardiographic, and functional standpoints. Total or almost total suppression of painful attacks was observed in four patients, while in three the attacks decreased in intensity and frequency. The effect of the drug was preventive and led to reduction or disappearance of the attacks in a few days. The effect was poor in two patients, in one of whom syphilitic coronaritis refractory to all symptomatic treatment was present, whereas the other had suffered a severe infarct. The arterial pressure of the patients was not influenced. The symptomatic action of Cromarile was studied in three persons who were subjected to the effort test. In all three, the test, which at first caused precordial pain, was painless after the administration of the drug. The electrocardiographic findings were improved in all the persons studied. Despite their limited experience, the authors state that the activity of 2-phenylchromone in dilating the coronaries from the functional as well as the symptomatic standpoint is extremely favorable, especially because doses that are effective are completely devoid of side-effects even when they are administered for months without interruption.

Clinical Experiences with a New 4-Oxycoumarin Derivative: Sintrom. S. Moeschlin and H. Schorno. Schweiz. med. Wchnschr. 85:590-592 (June 11) 1955 (In German) [Basel, Switzerland].

The new coumarin preparation, Sintrom (3-nitrophenylacetylethyl-4-oxycoumarin), takes an intermediate position between the coumarin preparations that have a prolonged effect and those that have a short action. The authors have used it since September, 1954, in 50 patients for the treatment of thrombosis, pulmonary embolism, and cardiac infarct, and to prevent thrombosis after operations or trauma. The drug is available in 4 mg. tablets, which can be divided. It is tasteless and is willingly taken in water or tea. The daily dose need not be divided but can be given at once. The prothrombin level increases within 24 hours and subsides to the initial values in from 48 to 72 hours. Therefore it is comparatively easy to adjust to the optimal prothrombin level without a too protracted time of recuperation, which can be further reduced by the administration of vitamin K_1. The new drug has practical advantages over other anticoagulants and is of great value in internal, surgical, and gynecologic conditions. No undesirable secondary effects were observed, even during prolonged treatment of up to six months.

Yeast Dermatoses During Antibiotic Therapy: III. Pathogenic and Therapeutic Study, with Particular Reference to the Incidence of Avitaminosis. P. de Graciansky, R. Leclerq, J. Delaporte and P. Gouin de Roumilly. Semaine hôp. Paris 31:2170-2182 (June 20) 1955 (In French) [Paris, France].

The various hypotheses proposed to explain the action of yeasts in certain untoward effects of antibiotic therapy are discussed, on the basis both of statements in the literature and of experiments conducted by the authors. Direct contact of various antibiotics with Candida albicans produced no noticeable effects on the latter, nor was there conclusive evidence that this organism acquires greater virulence when growing in the presence of an antibiotic agent. The administration of antibiotics to experimental animals does favor the germination of C. albicans, however. It must therefore be concluded that certain modifications of the terrain are induced, permitting the development of the disease caused by the yeast. The decimation of other organisms by the antibiotics with consequent disturbance of the floral distribution in favor of the pathogenic yeasts is a contributory factor but is not sufficient to explain the occurrence of the disease. The role of certain avitaminoses, notably that of avitaminosis B_2, seems to be established. The authors' experiments show that, contrary to past affirmation, vitamin B_2 does not possess fungistatic properties. Animals deficient in vitamin B_2 are definitely hypersensitive to infections caused by C. albicans, even when their deficiency is not enough to cause disturbances of the general condition. Two further factors mentioned in the literature, sensitivity to antibiotics and local irritation caused by antibiotics, do not appear to be important. Therapy of the yeast dermatoses caused by antibiotic treatment should consist not only of local and general applications of antifungal agents but of prophylaxis with the vitamin B complex.

BOOK REVIEWS

Denial of Illness: Symbolic and Physiological Aspects. By Edwin A. Weinstein, M.D., Associate Attending Neurologist, Mount Sinai Hospital, New York, and Robert L. Kahn, Ph.D., Research Psychologist, Mount Sinai Hospital, New York. Publication number 249, American Lecture Series, monograph in Bannerstone Division of American Lectures in Neurology. Edited by Charles D. Aring, M.D. Cloth. $4.75. Pp. 166. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1955.

This monograph represents the culmination of eight years of intensive investigation of the behavioral changes in brain disease, with use of .a combined neurological, psychiatric, and psychological approach. From many carefully controlled clinical studies of what superficially appear to be seemingly irrational behavior, the authors evolve clear evidence that denial of illness can be viewed as an orderly and understandable adaptation pattern to stress. This volume is a valuable monograph and carefully compiled, with adequate line drawings, complete references, and a valuable condensed table of clinical data of the 104 patients studied.

An introductory chapter considers the history of studies of denial of illness dating from the earliest cases described by Von Monakow in 1885, by Anton in 1896, and by Babinski in 1914. The authors then go on to describe the patterns of denial and list the following patterns of explicit verbal denial: (1) complete denial, (2) denial of major disability, (3) minimization or attribution to some benign cause, (4) projection of disability outside of the self, and (5) temporal displacement of the disability. They indicate that the denial of illness usually included more than one aspect of the illness, that the disability that was denied was not necessarily caused by a lesion of the nervous system, that patients with anosognosia for physical disabilities commonly denied the existence of other personal problems, and that confabulation was the device used to amplify the denial. The duration of anosognosia in patients varied from several days to one year; many patients who recovered showed amnesia for the period of denial. The patients with complete explicit denial showed no anxiety and were bland and affable during interviews. Other chapters consider the patterns of disorientation; reduplication manifestations; the language of denial; personality factors; anatomic and physiological factors; psychological studies; and experimental production of denial with special studies of the effects of barbiturates, the use of the Amytal test in the diagnosis of brain disease, and the effects of electric shock. A summarizing chapter also concerns itself with theoretical considerations.

The authors' data help to bury the ghost of overmeticulous cerebral localization, and they develop a comprehensive theory of the denial of illness as a reaction to stress. The book is highly recommended and should be read by every psychiatrist, neurologist, and internist.

How to Live Without Liquor. By Ralph A. Habas, Ph.D. With introduction by W. W. Bauer, M.D., Director, Bureau of Health Education, American Medical Association. Cloth. $2.50. Pp. 125. Farrar, Straus and Cudahy, 101 Fifth Ave., New York 3; Ambassador Books, Ltd., Toronto, Canada, 1955.

Although it has been designed for the general public, many physicians may read this little book with profit. While much of the factual information—for example, the description of the various medical treatments that may be used with the alcoholic—will be familiar, there is much material that is likely to prove enlightening and helpful to those without specialized training or with limited practical experience in coping with the liquor addict. In this category may be included the sections dealing with Alcoholics Anonymous, the therapeutic role of religion, the psychological and physiological factors involved in pathological or compulsive drinking, the special problems of the female drinker, and the agencies and facilities that are available to aid the alcoholic. This book's strongest claim to attention, however, lies in the fact that it can be heartily recommended to the problem or borderline drinker as well as to his or her relative, employer, or friend—indeed, to everyone directly or indirectly concerned with the liquor problem. The drinker himself, who, incidentally, is urged to see his family physician first, will find sympathetic understanding, wise counsel, practical guidance, and real encouragement in the pages of this book. Relatives and others anxious to assist the drinker will gain a better appreciation of his difficulties, receive sensible down-to-earth advice on how to treat him and influence him to take the necessary steps toward overcoming his addiction, and learn just where to go for specific information or personal assistance. For those who simply wish to become better informed on the grim but fascinating and vital problems of alcoholism, a reading of this lucid, nontechnical book will provide a rewarding survey of its most important practical aspects. In meeting this need, this unpretentious book can do much good.

Diseases of the Ear, Nose, and Throat in Children. By T. G. Wilson, M.B., B.Ch., Litt. D., Ear, Nose, and Throat Surgeon, Dr. Steevens' Hospital, Dublin, Ireland. Cloth. $12. Pp. 307, with 145 illustrations by author. Grune & Stratton, Inc., 381 Fourth Ave., New York 16; 99 Great Russell St., London, W.C.1, England, 1955.

This textbook should be a welcome addition to the libraries of otolaryngologists and pediatricians. The character of otolaryngological practice has changed greatly during the past generation because of the advent of sulfonamides, antibiotics, and antihistaminic drugs, and this has brought with it fresh emphasis on congenital defects, infantile otitis media, defective hearing and speech, the auditory and vocal rehabilitation of deaf children, and infections of the respiratory tract. Within the domains of otology, the relatively new science of audiology has developed. Readers of this book should find the chapters on congenital abnormalities of the ear, nose, face, esophagus, and lower respiratory tract useful and the chapters on deafness in childhood, the training and education of deaf children, defective speech in childhood, and thyroglossal cysts and fistulas informative. This book is highly recommended.

Pathology. By Peter A. Herbut, M.D., Professor of Pathology, Jefferson Medical College, Philadelphia. Cloth. $16. Pp. 1227, with 1378 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1955.

Professor Herbut states in the introduction to this book that it is intended for "the student of medicine—be he undergraduate or postgraduate" and indicates the general plan of the book. First, there is a brief survey of general pathology and then a full and systematic consideration of special pathology. The chapters in the latter section reflect the author's great interest in surgical pathology. All the important lesions and many unimportant ones are carefully described and illustrated. The book retells the traditional story of pathology from the familiar point of view of morbid anatomy, but pathology can be considered from other points of view, and of these the book makes little mention. Scant consideration is given to the mechanisms by which the lesions have been brought about, and there is only a small effort to explain them in terms of biochemical or biophysical alterations. The relative space devoted to general pathology and special pathology, which is in the ratio of about 1:10, seems disproportionate, and as a consequence the student is given only a bare description of the tissue changes and a list of the causes of such important phenomena as inflammation, degenerations, and tumors. Similarly in the chapters on special pathology little mention is made of the functional changes that accompany the anatomic changes. To illustrate, there is no discussion of abnormal liver or kidney function, although the morphological aspects of diseases of the liver and kidney are discussed in detail. The student who is willing to make allowances for these omissions will find the book a helpful guide to the identification of the evidences of disease that he will observe in the autopsy room and the laboratory of surgical pathology.

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

QUERIES AND MINOR NOTES

PAIN RELIEF DURING LABOR

To the Editor:—*A pregnant woman, who was a heroin addict, has been free of the addiction for 18 months. She is fearful of any pain-relieving medication during labor because of the possibility of renewing the drug habit. Is there any reason for concern if pain-relieving drugs are used sparingly during labor? If not, what about the use of barbiturates?*

M.D., New York.

This inquiry was referred to two consultants whose respective replies follow.—Ed.

Answer.—The patient well should fear renewal of her addiction if narcotics are used in labor. She should first be encouraged to believe she may need little or nothing in labor for relief of pain. Such methods employed by Grantly Dick Read, or even hypnosis if that is available may be helpful. To go through a labor without narcotics would strengthen her psychic resistance following her addiction. If these methods fail or are not available, barbiturates or any of the sedative nonnarcotic drugs may be used. Some obstetricians are using inhalant gas with considerable success.

One suggestion that may be helpful is the use of the new drug thorazine or chlorpromazine hydrochloride. When this drug is used, the dose of sedatives may be cut in half; in fact, one must use care in the dosage of any sedatives when this drug is used, because it enhances the effect so much one may oversedate the patient. When the second stage is reached, gas may be used, if necessary.

Answer.—There is no need to be concerned about the possibility of therapeutic use of pain-relieving drugs leading to relapse to opiate addiction, more particularly since the size of the doses used would be quite small. Addicts practically never relapse as a result of receiving analgesics postoperatively. Relapse is usually traceable to the same psychological and environmental factors initially responsible for the addiction. The same considerations apply to the use of barbiturates. If the patient insists on receiving no analgesics, small amounts of scopolamine might be tried. The use of some kind of regional anesthesia such as caudal analgesia might also be considered.

COMPLICATION OF PROLONGED CORTISONE TREATMENT

To the Editor:—*A 42-year-old white woman had been treated for severe arthritis for the past four years with cortisone, 25 to 50 mg. daily, and then she was referred to our clinic for a routine chest x-ray, which showed a massive pleural effusion in the left side of the chest. After aspirating the greater portion of this empyema, which was pea-green in color and very thick, we noted that there was no definite evidence of any parenchymal lesion that may have caused this empyema. There was no history of any previous pneumonia. A Mantoux test was negative, and the pus was negative for tubercle bacilli. Other examinations failed to reveal the cause of this empyema. Could a pleural empyema be caused by prolonged administration of cortisone?* *Louis Levin, M.D., Pontiac, Ill.*

Answer.—The case described presents one of the not uncommon and most distressing complications of prolonged cortisone treatment. The masking of the symptoms of an infectious process by cortisone administration has frequently been observed. In experimental animal and in humans it has been demonstrated that infections with organisms usually considered to be nonpathogenic or of very low virulence may occur when cortisone is administered in high dosage or over a long period of time. Preexisting infectious foci, particularly those of tuberculous etiology may flare up and produce a widespread systemic infection with minimal symptomatology under the influence of cortisone administration. Systemic infection with fungi ordinarily considered nonpathogenic have been reported in patients receiving cortisone. The reasons for this enhancement of susceptibility to infection seen in patients receiving cortisone (or other adrenal steroid) therapy are not entirely clear. Experimentally it can be shown that large doses of adrenal steroids may attenuate the immune processes that combat infection. It is also known that large doses of adrenal steroids may inhibit the repair processes of the body. In the case in question it would seem reasonable to postulate that the patient's resistance to infection was lowered by the chronic administration of cortisone with the consequent production of the empyema. Microscopic examination and culture of the pus for fungi such as Candida (Monilia) or Histoplasma capsulatum may help to establish the cause of this infection.

HEMOIRRADIATION

To the Editor:—*I received a letter about a patient who received irradiated blood by an instrument called a Knott hemoirradiator for myocardial infarction. The physician giving this treatment claims it is an accepted form of therapy in a number of medical conditions and quoted an extensive bibliography. I am not familiar with this instrument and would appreciate any information that you may give me as to its clinical usage, especially in coronary artery disease.*

Alexander A. Doerner, M.D., San Francisco.

Answer.—The Knott hemoirradiator is an apparatus that is employed to expose blood drawn from a patient to ultra violet light. This blood, presumed to have been modified by such exposure, is then returned to the patient as a therapeutic measure. This technique has been employed in a wide variety of diseases in which results are difficult to evaluate because of the inherent variability in the natural history of these disorders, e. g., biliary tract disease and pelvic cellulitis. Under such circumstances a protagonist could make a case for "benefit" from such therapy. It is, however, the general consensus that hemoirradiation by ultra violet light has not been demonstrated to be either on a firm theoretical, experimental, or clinical basis. The use of this technique for coronary artery disease is advocated by none of the authorities in this field throughout the country.

HEADACHES FROM DYNAMITE

To the Editor:—*A 35-year-old married man, in the course of his work, has occasion to handle dynamite. After handling the material, with his hands gloved, he invariably develops a violent headache. Furthermore, he tells me that the same type of headache will occur from merely wearing the gloves used in handling the dynamite, even though several weeks may elapse. I would appreciate an explanation of this phenomenon.* *Carl Stein, M.D., Loudonville, Ohio.*

Answer.—Nitroglycerin is readily absorbed through the human skin, if it comes in contact with the skin as from wearing "powder-contaminated" gloves. If the air contains nitroglycerin and similar nitrobodies, absorption by the lungs may add to the amount entering the body. The resulting dilation of cerebral blood vessels is presumably the mechanism of the nitrite headache. Rubber-impregnated gloves are sufficiently impervious to nitroglycerin to afford protection. These must be laundered in alkaline solutions daily or after each use to prevent their becoming a source of the drug (by contamination inside the glove).

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

MODERN CONCEPTS IN THE TREATMENT OF BURNS

Lieut. Col. Curtis P. Artz
and
Capt. Harry S. Soroff, (MC), U. S. Army

During the past 10 years significant advances have been made in the treatment of burns. Modern concepts of therapy are based on a more thorough understanding of the physiological derangements that occur after burning.

APPRAISAL OF THE BURNED PATIENT

The magnitude of injury is based upon two principal factors, extent of injury and depth of burn. The extent of burn is usually expressed as the percentage of the total body surface area. For many years, Berkow's table was used as a guide for estimating the percentage of body surface burned. A modification of this table by Tennison and Pulaski into the "rule of nines" has been employed recently (see figure).[1] For children, the extent of burn should be increased for the head and trunk and decreased for the extremities.

Burns are usually divided into three categories based on depth: first degree, second degree, and third degree. A first degree burn is characterized by erythema and involves only the outer layer of the epidermis. Healing usually occurs uneventfully in two to five days. It is sometimes very difficult for the most experienced surgeon to distinguish between second degree and third degree injury. Characteristic features of these two depths of burns are shown in table 1. Since the systemic derangements and prognosis are directly related to the amount of tissue destroyed, it is obvious that the full-thickness burn is more serious than a second degree burn of similar extent. It is difficult to assess the exact relation of severity of second degree to third degree burns. In a recent study of 323 hospitalized burned patients, Schwartz and co-workers [1a] have shown that the best correlation between case fatality rate and survival time can be achieved when the percentage of second degree injury is given one-half the weight, area for area, of the percentage of third degree injury. These investigators have suggested a burn index that is calculated by assessing one point for each per cent of third degree injury and one-half point for each per cent of second degree injury. This means that in a mixed burn with 30% third degree and 20% second degree injury the index is 30 plus one-half of 20, or 40. In this same series treated during the past four years, the case fatality rate was 50% for patients who had an index of 45. This simple index serves as a practical guide for severity of injury.

In appraising severity, other factors in addition to the extent and depth of the injury must be considered. Burns in some parts of the body are followed by such crippling defects that they should be regarded as serious even if they are of small extent. These areas of functional importance are the face, hands, feet, external genitals, and flexion creases. If the burn is complicated by a fracture or soft-tissue injury, it decreases considerably the chance of survival and increases the difficulties of treatment. The age and general physical condition of the patient before the burning accident also contribute to the seriousness of the injury. Greater risks are involved in infants and elderly adults. Patients who have renal, cardiovascular, or pulmonary diseases show poor tolerance for burns, even of minor extent. Burns of the respiratory tract are particularly serious, irrespective of the amount of surface area involved.

DISPOSITION OF THE BURNED PATIENT

For treatment purposes burned patients can be divided conveniently into three groups: (1) those with critical burns who should be referred to a well-equipped general hospital where a surgeon experienced in burn care is available, (2) those with moderate burns who may be treated in a small community hospital, and (3) those with minor burns who may be treated on an outpatient basis. Critical burns include: (1) burns complicated by respiratory tract injury; (2) partial-thickness burns of more than 30% of the body surface; (3) full-thickness burns of the face, hands, feet, genitals, or of more than 10% of the body surface; (4) burns complicated by fractures or major soft-tissue injury; and (5)

From the Surgical Research Unit, Brooke Army Medical Center, Fort Sam Houston, Texas.

Read before the Joint Meeting of the Section on Military Medicine and the Section on Surgery, General and Abdominal, at the 104th Annual Meeting of the American Medical Association, Atlantic City, June 9, 1955.

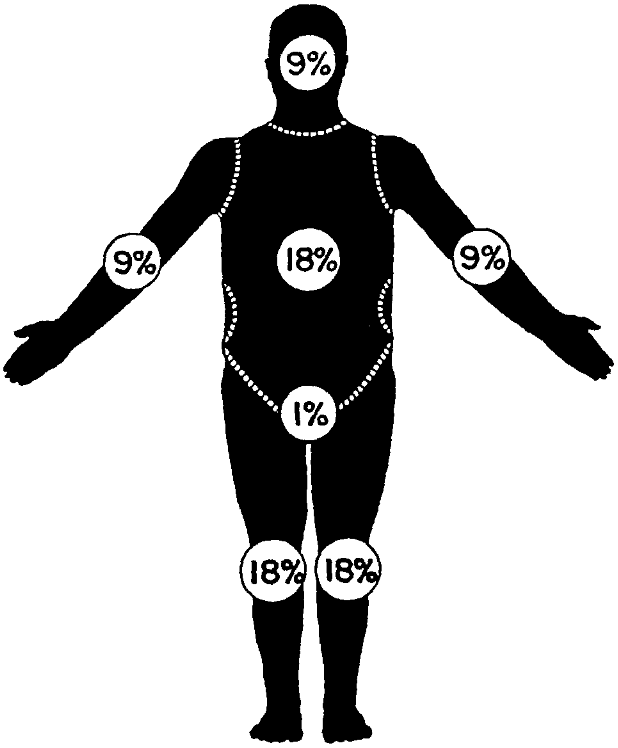
[1a] Schwartz, M.; Soroff, H. S.; Reiss, E., and Artz, C. P.: Analysis of Mortality at the Surgical Research Unit, unpublished data.

electrical burns. Moderate burns include: (1) partial-thickness burns of 15 to 30% of the body surface, and (2) full-thickness burns of less than 10% of the body surface if the hands, face, feet, or genitals are not involved. Minor burns include partial-thickness burns of less than 15% of the body surface and full-thickness burns of less than 2% of the body surface for which the person may be treated as an outpatient and hospitalized later for minor grafting.

Treatment of Burns in Outpatients.—In minor burns, the injured surface should be cleansed with a mild soap and water; all blisters should be broken, and loose, devitalized epithelium should be removed. Masks should be worn by attendants, and an aseptic technique should be carried out. Minor burns of the face may be exposed. Burns of all other areas should be dressed. The burned surface should be covered with fine-mesh gauze, lightly impregnated with petrolatum; then a large, bulky, occlusive dressing should be applied. The affected parts should be bandaged in a position of function and immobilized. Prophylaxis against tetanus should be administered, and, in most instances, antibiotics should be given for three to five days. The dressings should be changed in 5 to 10 days.



Rule of nines: The body is divided into various segments, each representing 9% or multiples thereof. The head and each arm are given 9%; the anterior trunk, posterior trunk, and both lower extremities are given double 9, or 18%; and the genitals are given 1%.

Care of Hospitalized Burned Patients.—Patients with moderate or critical burns should be given emergency treatment and transported to a hospital immediately. If transportation requires less than one-half hour, the patient may be given a small dose of morphine intravenously and the burned areas covered with a clean sheet to prevent further contamination. If transportation requires a longer period, infusion of a plasma volume expander, or lactated Ringer's solution or dextrose in isotonic sodium chloride solution should be started. Patients may be transported several hundred miles by air during the first 24 hours without deleterious effects, providing fluid and electrolyte requirements are fulfilled in transit. Physiological derangements grow progressively worse after injury, so that burned patients do not tolerate prolonged transportation as well after 48 hours as they do during the first 24 hours.

Immediate Hospital Treatment.—General supportive care should take precedence over treatment of the local burn wound. Morphine may be indicated for pain. I it is used, it should be given intravenously in a dose o 8 to 10 mg. Severely burned patients frequently thras about and are most uncooperative because of cerebra anoxia rather than pain. The immediate and rapid infusion of a sufficient amount of a plasma volume expander *frequently transforms an unruly patient into* quiet and cooperative individual. In major burns o more than 25% of the body surface, a cannula shoul be inserted and a Foley catheter should be placed i the bladder. A cannula may provide a satisfactory port for the infusion of fluids. In some severely burned patients, the insertion of a 14-gauge needle into the femor vein will permit a segment of plastic tubing to b threaded through it into the inferior vena cava. Aft removal of the needle the tubing left in the vein provid an excellent means for constant infusion of lar amounts of fluid. The segment of tubing should carefully measured and its length recorded in order be assured that all the tubing has been pulled out of t vein when the cannula is no longer needed. This plast tubing should not be left in place more than 7 to 14 da because it might give rise to thrombosis and pulmona emboli.

TABLE 1.—*Characteristic Features of Second and Third Degree Burns*

Characteristic	2d Degree	3d Degree
Etiology	Hot liquids, short flash	Flame
Color	Pink or mottled red	Pearly white or charred
Surface	Blisters or weeping	Dry
Sensitivity	Painful or hypesthetic	Anesthetic

In the event that respiratory damage is suspected, immediate tracheotomy should be performed. This pr cedure should be carried out as soon as there is suspici of tracheobronchial damage. To delay until there positive evidence of respiratory difficulty may be t late. A tracheotomy should also be performed whe there is a full-thickness burn of the face. Tetanus pr phylaxis should be administered and antibiotic therap instituted. During the first 48 hours, administration one million units of penicillin and 1 gm. of streptomyci intravenously every 12 hours seems to provide excelle prophylaxis against infection. Therapy with penicilli and streptomycin may be continued intramuscularly afte the first two days unless there is evidence that uncontrolled infection is developing. In such instances, on should use a broad-spectrum antibiotic, selected according to the sensitivity of the bacteria cultured from th wound surfaces or the blood stream.

SUPPORTIVE THERAPY

It is customary to think of a burn as a two-dimensional wound-involving area, rather than in terms of depth or volume. Burns are characterized by capillary damage. The third dimension of the burn wound or volume of tissues in which capillaries are functionally deranged is one of the most important factors in understanding replacement therapy. Edema follows burning because of vasodilatation and increased capillary permeability. Contrary to general belief, the visible surface losses constitute but a small fraction of the fluid lost from the effective circulation. Most of this fluid that is lost functionally is sequestrated beneath the burn wound. Third degree burns are even more misleading. They are characterized by a dry surface. The hard eschar may prevent obvious edema; nevertheless large volumes of fluid extravasate into the deep tissues.

Fluid and Electrolyte Therapy.—In general, burns in adults that involve less than 15% of the body surface require only a minimum of supportive therapy. Colloid solutions are not necessary, and fluid requirements are satisfactorily met by an orally given electrolyte solution. A well-refrigerated salt-soda solution containing 3 gm. of sodium chloride and 1.5 gm. of sodium bicarbonate per liter given orally is well tolerated by most patients. This solution is hypotonic and contains 70 mEq. of sodium per liter. Isotonic electrolyte solutions are unpalatable and poorly tolerated when administered orally.

Surface Area Formulas: Intravenous replacement therapy is required in more extensive burns. Several formulas have been devised by different clinics for estimating the amount of fluids required.[2] All the formulas seem to serve as useful guides because they offer an adequate amount of fluids, and the physicians using them should make variations according to the needs of each individual patient. A formula should be used to outline a plan of treatment and not as a strict guide for the exact amount of fluids to be administered. Some formulas consist almost entirely of colloids, and others favor a predominance of electrolytes. During the past four years, a middle-of-the-road formula has been used successfully by the Surgical Research Unit.[3] The colloids and electrolytes required are based on the weight of the patient and the percentage of body surface burned. The requirements for the first 24 hours are computed as follows: colloid, 0.5 cc. per kilogram of body weight for each per cent of body surface burned; electrolytes, 1.5 cc. per kilogram for each per cent of body surface burned; and approximately 2,000 cc. of glucose in water. Since the relationship between fluid requirements and percentage of burn is not linear throughout, the requirements for burns involving more than 50% of the body surface are calculated as though only 50% had been burned.

The requirements for colloids in second degree burns can easily be fulfilled by the use of virus-free plasma or a plasma volume expander, such as dextran. Whole blood is the colloid of choice in third degree burns. The electrolyte requirements are best fulfilled by the use of a balanced salt solution, such as lactated Ringer's, rather than glucose in 0.9% saline solution. Extensively burned patients have a tendency to develop a metabolic acidosis, and the increase in the chloride ion following infusion of 0.9% saline solution only tends to potentiate this acidosis. Since fluid losses are more rapid in the first few hours after injury, approximately one-half of the estimated requirements of fluids for the first 24 hours should be given in the first 8 hours. An increased amount of colloids may be required in patients who are first seen several hours after injury. In such patients, the rate of administration should be rather rapid in order that replacement therapy may catch up with fluid losses. In the second 24-hour period, requirements of colloids and electrolytes are approximately one-half those of the first 24 hours. In addition, the patient needs approximately 2,000 cc. of glucose in water.

After estimates of fluid therapy have been made by use of the formula, the final judgment as to rate and type of solutions administered should be based upon the clinical response of the patient. More rapid administration of fluids is required if the blood pressure is falling and the urinary output falls below 30 cc. per hour. It is not true, however, that the greater the flow of urine the better the therapy. Since fluid leaks from the vascular tree as it is infused, the interstitial space will be excessively expanded if sufficient quantities of fluid are given in order to maintain a urinary flow of more than 50 cc. per hour. If the urinary output exceeds 50 cc. per hour, the rate of infusion should be decreased. Patients who have respiratory involvement or elderly patients should be given minimal quantities of fluid. These patients should receive the smallest amount of fluid possible to insure an adequate renal filtration pressure. The serum sodium determinations may be of value during the second 24 hours. Therapy during this period should be continued with colloids, electrolytes, and water in quantities sufficient to maintain a satisfactory urinary output and a serum sodium level that does not exceed 140 mEq. per liter; a serum sodium level of 135 mEq. per liter is optimum.

Replacement After Forty-Eight Hours: After 48 hours, the patient with moderate burns is usually able to take food and fluids by mouth and will adjust his intake to his needs; however, in critically burned patients the real difficulties in fluid and electrolyte imbalances occur from the 3rd to the 12th day. During this period, the serum sodium level rather than urine output seems to be the best guide to therapy. An adequate amount of free water must be given intravenously to make sure that the serum sodium level does not rise to within the range of 150 to 160 mEq. per liter. Such an elevated serum sodium concentration means hypertonicity of the interstitial fluid. The hypertonicity of this fluid may withdraw water from the cells and lead to intracellular dehydration and death.

Resorption of edema fluid in extensively burned patients may require several days. During the prolonged period of diuresis the insensible water loss appears to be in the magnitude of 1,500 to 2,000 cc. per day. During this period, when the sodium load that was given during the first 48 hours is being excreted, electrolyte-free water should be given in sufficient quantities to maintain a dilution of the serum sodium of about 135 mEq. per liter. If proper amounts of fluid are given in the first 48 to 72 hours, acute renal insufficiency rarely occurs except in overwhelming deep burns of some 70 to 80% of the body surface. After the first 48 hours, the hematocrit serves as a good guide to the adequacy of blood volume. Sufficient blood transfusions should be given to maintain a hematocrit of approximately 45%.

When food is not tolerated by mouth, administration of potassium should be started during the second or third day and continued until an oral dietary intake has been established. As long as a patient maintains a good urinary output, there should be little fear of overdosage with potassium. From 80 to 130 mEq. of potassium is a satisfactory intravenous daily requirement.

General Nutrition.—A tremendous loss of nitrogen occurs after a burn. In detailed metabolic balance studies of eight patients (average extent of burn 40%, of which 19% was full-thickness) Reiss and co-workers [4] found that the average duration of the catabolic phase was 33 days. The average daily nitrogen loss for this period was 25.6 gm. Although these patients were encouraged to take a maximum diet, the average daily intake was only 15.2 gm. of nitrogen and 3,000 calories. The average negative nitrogen balance during the catabolic period was 10.4 gm. per day, or a protein deficiency of approximately 65 gm. In spite of this tremendous negative nitrogen balance, the wounds healed well and skin grafts took well.

It is a common observation that burn wounds of individuals who were healthy previously seem to heal well even in the presence of a negative nitrogen balance for the first 30 to 40 days after the burn was incurred. Interference with wound healing does not seem to occur until a prolonged period after injury, at which time extreme depletion may well have occurred. Positive nitrogen balance in the burned patient can readily be achieved as soon as the wounds are healed. Extensively burned patients lose about 1 lb. (0.5 kg.) of weight per day during their period of catabolism. On the other hand, it is not uncommon to see a patient gain 1 lb. per day after the wounds have been closed and the patient is ambulatory.

The aim in the nutrition of burns should be to maintain a maximum intake of proteins, calories, and vitamins. This usually can be achieved by a high-protein, high-caloric diet that is supplemented by a between-meal high-protein liquid intake. In some patients, it may be necessary to insert a nasogastric tube and give a high-protein, high-caloric liquid feeding directly into the stomach. Intragastric tube feedings should be withheld until after the first week. Severely burned patients usually have a gastrointestinal atony for the first few days following injury and they do not tolerate tube feedings. Vomiting and aspiration are not uncommon complications of tube feedings shortly after a burn.

Contraindications for Hormone Therapy.—It is a common misconception that corticotropin (ACTH) and cortisone therapy for the acute burn will do little harm and may be of some general supportive value. There is ample evidence that the administration of corticotropin or cortisone diminishes the patient's resistance to infection.[5] There is no substantial evidence at present that this type of therapy is of any value except in rare instances where it is proved that adrenal insufficiency is present. There is evidence that the patient liberates enough adrenocortical hormone after the severe insult of a burn to make additional hormone therapy unnecessary.[6] Since infection is one of the chief problems in burns, it would seem that any type of medication that might decrease the patient's resistance to infection would be strongly contraindicated.

LOCAL CARE OF THE BURN WOUND

The primary aims of local care are the prevention and control of infection and the closure of the contaminated wound as soon as possible. After correction of the physiological derangements, attention may be directed toward the cleansing of the wound. Every effort should be made to minimize further contamination.

Initial Cleansing.—The patient should be taken to a clean dressing room or operating room where a strictly aseptic technique can be carried out. Usually analgesia induced by intravenously given morphine is sufficient, hence anesthesia with its further risks may be avoided. The cleansing technique produces considerable discomfort but little pain. The burned area should be cleansed thoroughly and all debris and detached epidermis should be removed.

Definitive Local Care: After the burn wound has been made as clean as possible, a decision must be made as to the type of definitive local care. There are two main techniques, exposure and occlusive dressings.[7] These two methods do not constitute two distinct schools of thought, but they are techniques that may be used to complement each other. Neither method is ideal; both have certain advantages and disadvantages. The occlusive dressing method is applicable to all areas, but exposure is not, because certain burns may be of such configuration that adequate exposure cannot be achieved. Under such circumstances, it may be wise to expose some areas and dress others in the same patient. One of the chief advantages of exposure seems to be a more effective control of infection. The warm, moist, dark environment beneath a dressing is conducive to bacterial reproduction. Deep dermal burns, treated by exposure, become dry and usually heal uneventfully, but when treated by dressings they may become infected and result in full-thickness injury. Exposure permits frequent observation of the wound and earlier detection of infection.

During the first 48 hours after exposure, patients have pain and complain of chilling; but they are quite comfortable after the protective covering has formed. Discomfort is minimized if drafts are avoided and if the ward is kept at an even temperature. When dressings are applied immediately after injury, there is freedom from pain and the patient is less likely to be uncomfortable. After a few days, however, the patient who has had his wounds dressed often develops a higher fever and complains of greater discomfort. Dressings permit better immobilization than exposure. The exact depth of the burn can usually be ascertained earlier when the dressing method is used than when the burn is exposed. This undoubtedly permits removal of the eschar a few days earlier. Since exposure is applicable only to burns and not to any other open wounds, the coexistence of soft tissue wounds and burns at the same site contraindicates exposure.

In the moderate-sized burn there is little difference in the nursing care required by either method. In very extensive burns, particularly when exposed patients must be turned on a Stryker frame, the nursing care of the exposed burn is increased considerably. On the other hand, exposure eliminates the necessity of frequent dressing changes by the physician. Undoubtedly one of the chief advantages of the exposure method that is rarely recognized is that frequent use of anesthetics and frequent dressing changes can be avoided. The detrimental effects of frequent anesthesia in a severely injured patient are well recognized. In major burns of 40 to 60% of the body surface, almost invariably an anesthetic is required for a dressing change. Dressing changes may be necessary at two-day or three-day intervals to keep the wound surface clean, dry, and free from suppuration. In such instances, frequent anesthesia is deleterious to the condition of an extensively burned patient. On the other hand, when exposure is used, no anesthetic is necessary until the eschar is finally removed. A better positioning of the hands and less edema is possible when a dressing is applied; however, after observing several patients who had one hand exposed and the other dressed, it was noted that patients usually prefer exposure because they really dread the pain associated with even the gentlest dressing change.

Almost all partial-thickness burns do extremely well when treated by exposure. This method is certainly preferred for burns of the face, burns of the perineum, and burns of one side of the body. The method of definitive local care should be selected for each particular patient in accordance with the surgeon's experience and the exigencies of the situation. Both methods yield excellent results when applied properly.

Exposure Technique: After initial cleansing of the burn wound, the patient may be placed in bed on clean, nonsterile sheets in the most comfortable position that adequately exposes the affected areas. The exudate of a partial-thickness burn dries in 48 to 72 hours and forms a hard crust that serves as a natural protective cover for the wound. During this time, small doses of a narcotic may be necessary. Epithelial regeneration proceeds beneath this crust and is usually complete in 14 to 21 days. In full-thickness burns there is dehydration of the pearly white or charred dead skin, and it is converted into a protective eschar in 48 to 72 hours after exposure. This eschar serves as a temporary physiological cover until liquefaction occurs beneath it in 14 to 21 days.

If cracks should occur in the eschar, the open area should be covered with a piece of moist, fine-mesh gauze in order that a new covering may form. If suppuration is spreading, the eschar must be removed and dressings should be applied. Treatment by exposure ends in partial-thickness burns when the protective covering falls off and complete healing has been achieved. In full-thickness burns, it ends when eschar removal has been accomplished; granulating surfaces should never be exposed.

Occlusive Dressing Technique: When Allen and Koch[8] introduced occlusive dressings in 1942, it was believed that firm mechanical pressure inhibited the amount of exudate that flowed from the wound and thereby decreased the fluid loss. In recent experiments there has been no evidence that such pressure decreases fluid losses; it only shifts the collection of fluid to the interstitial spaces proximal to the wound.[9] Dressings should be applied with even, resilient compression in such a way that there is elimination of dead spaces and a splinting effect. The initial layer should be gauze lightly impregnated with petrolatum, and the dressing should be bulky to provide maximum absorption.

The time for subsequent dressing change is regulated by the necessity for keeping the wound as clean as possible. In some partial-thickness burns, an adequate dressing can be left in place for 10 days, while in other burns the dressings may need to be changed as frequently as every other day. The dressings should be changed whenever there is undue malodor, increased pain, soaked dressings, or an unexplained elevation of temperature. The dressing change should be performed under sterile conditions, preferably in an operating room. Every effort should be made to eliminate anesthesia. Many dressings may be changed with the aid of analgesia induced with intravenously given morphine.

It is doubtful if an antibiotic ointment is of any appreciable value when applied initially to the burn wound. If local infection develops, however, a specific antibiotic ointment is indicated. The choice of antibiotics should be made according to the sensitivity of the bacteria found on the burned surface. Maximum benefits from antibiotic dressings can be achieved only when they are changed every two days, because antibiotics applied locally seem to be effective for only about 48 hours.[10]

Removal of Eschar and Grafting.—In burns of less than 5% of the body surface that can unquestionably be diagnosed as third degree, primary excision of the full-thickness injury and immediate application of a split-thickness skin graft may be carried out. On the other hand, in the case of large burns when the life of the patient is questionable and the availability of skin is scarce, the eschar should be allowed to remain in place until most of the surrounding partial-thickness burn has healed. This usually occurs about the 14th to the 21st day. In moderate-sized burns and in third degree burns of the hands or around joints, the areas may be excised earlier. In very extensive burns, removal of the eschar should be carried out with the least possible trauma to the patient. It may be necessary to wait until natural sequestration has occurred and a good granulating barrier has formed beneath the eschar. The aim should be to remove the eschar as soon as possible without jeopardizing the patient's chances for survival. After removing the eschar, a dressing should be applied and skin grafting should be performed as soon as the granulating surface is properly prepared. The use of large sheets of skin taken with the electric dermatome is a most expeditious way of covering large burned surfaces.

12	55	60	40	None	Septicemia	Yes	20	Duodenum	Asymptomatic

Exposure of Donor Sites: An accepted method for the management of donor sites is the use of occlusive dressings. As long as the wound is kept free from infection, healing occurs. Motion, mechanical trauma, and infection are the chief deterrents to proper healing. Bacterial proliferation is not uncommon under a dressing that becomes warm and moist. This is particularly true in hot, humid climates. In extensive burns, it is difficult to apply an occlusive dressing and isolate donor areas that are interspersed between infected granulating surfaces. Donor sites heal uneventfully in most instances if properly exposed.[11] Upon removal of the skin, the donor area should be covered with dry, fine-mesh gauze. A hot, moist gauze pad may be applied until hemostasis is achieved. The area is then exposed to the air, and within 24 hours a coagulum forms from the blood in the interstices of the fine-mesh gauze. This serves as a protective covering for the wound. Healing progresses beneath this coagulum, and the covering falls off in 14 to 20 days, leaving a well-epithelized surface.

Postmortem Homografts: When large areas require grafting, skin for autografts may not be available. In some debilitated patients, the removal of the patient's own skin may be contraindicated. Temporary closure of the wound by a homograft prevents infection and further deterioration of the patient by reducing the amount of fluid, electrolyte, and protein losses. The advantages of postmortem homografts over homografts from living donors are obvious.[12] Postmortem homografts may be removed from the body of a deceased person under aseptic conditions soon after death, preferably within the first six hours. After the skin is removed, it may be stored in a refrigerator at approximately 4 C for as long as seven to nine days. Disintegration of the homograft begins about the 21st day, and the average survival time is about 30 days. As the homografts disappear, they may be replaced with the patient's own skin until areas of full-thickness loss are covered.

OUTSTANDING PROBLEMS IN MANAGEMENT OF BURNS

For many years, toxemia has been the term used to describe a syndrome associated with burns, characterized by disorientation, gastrointestinal atony, high fever, tachycardia, increased respiratory rate, diminishing urinary output, coma, and death. It has been postulated that this toxemia is the result of the absorption of a foreign protein from the dead tissue of the burned surface. In the past few years there has been evidence that this syndrome is directly associated with septicemia.[13] In reality, so-called toxemia of burns is often a septicemia.

[13] Liedberg, N. C. F.; Reiss, E., and Artz, C. P.: Infection in Burns: III. Septicemia, a Common Cause of Death, Surg., Gynec. & Obst. **99**: 151 (Aug.) 1954.

Septicemia.—In the management of more than 800 burns during the past five years at the Surgical Research Unit, there have been 53 deaths. The causes of death are outlined in table 2. The high incidence of septicemia, as proved by repeated positive blood cultures or by autopsy findings, attests to the predominance of this factor as a problem in burn therapy. As replacement therapy improves, a greater number of extensively burned patients survive the early period after injury but develop septicemia later. The route of entrance of the invading organisms is most likely through the extensively injured surface. At present, the aims in the treatment of septicemia are early skin coverage by autografts or postmortem homografts, optimal fluid and nutritional supportive therapy, and massive doses of antibiotics.

Duodenal Ulcer.—As a larger percentage of extensively burned patients survive because of improvements in supportive therapy, there appears to be an increase in the incidence of gastrointestinal ulcerations.[14] These acute ulcerations in the upper part of the gastrointestinal tract seem to follow the unusually severe stress in extensive burns. During the past five years, 12 patients were observed who had duodenal ulcer due to burns (Curling's ulcer) (table 3). Three of these patients survived massive gastrointestinal hemorrhage, and all evidences of ulcers disappeared upon improvement in general condition and coverage of the burned surface. These patients were treated with adequate blood replacement and antacid therapy. In the nine patients who died, four deaths were directly attributable to perforation or hemorrhage from the ulcer and five deaths occurred from other causes. The intense response of the body to an overwhelming burn may lead to the formation of acute gastrointestinal ulcerations.

SUMMARY

Modern concepts of burn therapy include time-honored surgical principles of supportive therapy, prevention of infection, and early closure of the wound. A better understanding of replacement therapy, particularly in the period after the first 48 hours, has led to an increased survival rate. Two techniques of local care, the exposure method and occlusive dressing method, complement each other in the treatment of the burn wound; the exposure method can also be applied in the management of donor sites. Postmortem homografts are of considerable value in the extensively burned patient, as they furnish a temporary cover for the large granulating surface. During the past five years, there have been 53 deaths among more than 800 hospitalized burned patients. Septicemia has been directly associated with 30 of these deaths. Duodenal ulcer due to burns (Curling's ulcer) has been present in 12 patients, 9 of whom died.

BASIC PRINCIPLES IN MANAGEMENT OF OPEN FRACTURES

Oscar P. Hampton Jr., M.D., St. Louis

An open wound communicating with a fracture site complicates management of the injury for several reasons. Blood loss may cause shock and seriously delay the definitive management of the wound and fracture. Loss of the hematoma from the fracture site may retard union of the fracture. Damage to the soft tissues may limit the eventual return of function of the part. The principal hazards of open fractures, however, are those of secondary infection and failure of healing of the wound and the fracture.

Infection of the wound may develop in several ways. There may be a true invasive infection of living tissue by bacteria, primarily or secondarily implanted in the wound. Invasive infections of which gas gangrene is an example usually take origin in dead and devitalized tissue in the wound. A second type of wound infection, much more common than true invasive bacterial infection, results from the bacterial decomposition of devitalized soft tissue and blood clot with resulting suppuration. The necrotizing enzymes in the pus thus formed cause further destruction of living soft tissue and bone that in turn leads to more suppuration in a vicious circle. In other instances, a true wound infection is not present in the beginning, but the loss of soft tissue or a gaping, open wound may leave bone, fascia, or tendon exposed. These tissues cannot survive if they remain exposed in a wound. They soon die and become the nidus for wound suppuration. The ultimate effect of an open wound in which these vulnerable tissues remain exposed, then, is really a wound infection beginning in dead tissue. A common denominator in all these wound infections is retained dead and devitalized tissue, truly the pabulum of sepsis.

OBJECTIVES

Basic objectives of the management of open fractures include the prevention or eradication of wound infection and healing of the fracture in good position without further death and loss of tissue. It readily follows that, to achieve these objectives, underlying factors leading to wound infection must be eliminated. The wound must be thoroughly débrided. The depths and recesses of the wound must be thoroughly cleaned of dirt, debris, and foreign material during the so-called contaminated period before active bacterial infection can develop. Contaminated dead and devitalized tissue, which actually includes old blood clots, must be surgically excised before it can be decomposed into pus. Then, those tissues that cannot survive if they

Read before the Joint Meeting of the Section on Military Medicine and the Section on Surgery, General and Abdominal, at the 104th Annual Meeting of the American Medical Association, Atlantic City, June 9, 1955.

remain exposed must be covered if surgically feasible with healthy, soft parts before they undergo necrosis.

Insofar as the management of a broken bone is concerned, the fragments must be placed and held in adequate apposition and alignment. Adequate reduction not only favors union of the fracture with minimal deformity but also is an additional measure against wound infection. A septic fracture is usually an unreduced fracture. With the fragments held in good position, dead space in which contaminated blood clot and wound exudate can collect is avoided, pressure of fragments against the underneath surface of the skin that might cause tissue necrosis does not occur, wound margins are more easily approximated without tension, and repeated traumatizing efforts at reduction are unnecessary. In these ways, reduction of the fracture inhibits wound infection.

BASIC PRINCIPLES

In seeking these objectives, the physician must handle open fractures as true surgical emergencies. These open fractures require prompt, thorough investigation, appraisal, and treatment in a fully equipped operating room and not merely a haphazard incomplete examination in an emergency room. With any systemic effects of hemorrhage or wound shock having been previously overcome and with adequate x-ray studies visualizing the entire length of the broken bone having been made, the part is surgically cleaned and prepared (soap and water preparation is all that is necessary, as antiseptics are not advisable) and the wound is thoroughly examined. As a rule, general or spinal anesthesia is necessary. An appraisal of the degree of contamination of the wound and the amount of damaged tissue probably remaining in it serves to determine the surgery that is indicated.

Wound Débridement.—In the technique of wound débridement, exposure of the depths of the wound must be ample. Inadequate exposure leads to inadequate débridement. As a rule, the wound must be extended in the direction that will afford adequate access to the depths of the wound and still facilitate closure by suture but at the same time avoid unnecessary exposure of tissues likely to die if they remain uncovered. In the extremities, incisions are usually parallel to the long axis of the limb. Circular skin incisions around the margins of a wound, the so-called wound circumcisions, are inexcusable. Incisions should not cross the center of a wound that runs in the opposite direction so as to create a crucial incision. When proximal and distal incisions from a transverse or circular wound are indicated, they should begin at opposite corners of the wound so as to leave, in effect, a Z-shaped incision. This kind of an incision is particularly advantageous in areas in which the skin is normally tight, such as over the anterior surface of the leg.

After an ample skin incision has been made, the dead and devitalized tissue must be excised. Healthy muscle is not discolored, bleeds freely, and contracts when pinched; muscle that does not meet these requirements warrants excision. Foreign bodies and dirt are removed. Thorough irrigation of the wound is a valuable cleansing method. Small fragments of cortical bone completely free of soft tissue attachment may be excised; fragments that have any soft tissue attachment at all should be carefully preserved. Sponging in the area of the fracture must be done with great care. Jagged fragments easily catch in the meshes of a sponge and may be avulsed from their soft tissue attachments when the sponge is removed from the wound.

Closure.—After the wound has been made as surgically clean as is technically possible, a decision concerning immediate suture must be made. Closure of the wound of an open fracture by suture at the proper time is highly desirable not only to minimize scar but to protect those tissues that are vulnerable to exposure and to avoid secondary contamination. The decision to suture the wound, however, must be based upon sound surgical judgment. Too much has been said about the immediate closure of wounds of open fractures so as to quickly convert each open into a closed fracture. Of course, an immediate successful suture of the wound is most advantageous but an unsuccessful suture because of abscess formation or necrosis of skin margin due to excessive tension is worse than if the wound hac been left open to granulate to healing. The price o either of these complications is additional soft tissu necrosis that further retards and may prevent woun healing.

In surgery for civilians, suture of a clean, wel débrided wound of an open fracture is frequently feas ble, particularly if the time lag after injury is not to prolonged (many wounds may be closed primarily u to 12 to 16 hours after injury), and closure is definite and surgically feasible without excessive tension bot at the time of closure and later after swelling of wour margins has occurred. On the other hand, if the su geon cannot be certain that the wound is rid of tl pabulum of sepsis or if closure by suture might lead excessive tension on the skin margins, particularly aft swelling has taken place, then an open wound is high preferable despite its inherent hazards. A long, ful thickness, relaxing incision parallel to but several inch from the suture line is at times a valuable way of relie ing excessive tension. If the decision is made to leav the wound open, delayed primary closure should b performed if surgically feasible between the fourth an seventh day, provided the wound is clinically clear Delayed closure of clinically clean wounds is surgicall sound, provided dead space is obliterated or depend ently drained and excessive tension is avoided. Th problem of surgical closure, primary or delayed, of a open wound of a fracture versus the advantages of a open wound for drainage as a safeguard against deej infection (including anaerobic infection) is one tha may severely tax the judgment of even the most ex perienced surgeon.

COMMENT

Do all open fractures require wide open exposure anc débridement as a safeguard against wound infection? Undoubtedly in many open fractures, usually those opened from within-out, the surgeon can be reasonably certain from the circumstances of the accident, the appearance of the wound, and the clothing about the site of injury that no foreign material has been carried into the wound and that soft tissue damage is minimal. Under these circumstances, the factors discussed above that predispose to wound infection are probably not present. In such instances, the surgeon may elect to thoroughly irrigate the wound with sterile saline solution, suture the skin margins or merely apply a sterile dressing, reduce the fracture by closed methods, and apply immobilization. While such practices cannot be condemned, it is to be pointed out that they are a calculated risk. In the majority of open fractures, some débridement of the depths of the wound is definitely indicated. Insofar as the fracture is concerned, the same methods of management are applicable in general to open as to closed fractures. In open fractures, however, the question of employing internal fixation at the time of débridement of the wound often assumes paramount importance. As the wound is explored and cleaned, the fracture site often comes into view. If the contour of the fracture is such as to permit adequate stabilization by internal fixation, the decision regarding it must be made immediately. This, too, is a problem that requires expert decision.

As a practical matter, in well-débrided wounds that can be closed by suture or in which heavy masses of muscle tissue will fall over and protect bone and metal from exposure, there need be little hesitancy in applying internal fixation to the fracture through the open wound if internal fixation is otherwise indicated. Methods of internal fixation that require little or no periosteal stripping, such as intramedullary fixation or multiple screw fixation, appear highly preferable to plating. If, on the other hand, factors likely to lead to infection of the wound are present, internal fixation is probably too hazardous. In doubtful cases, it is advisable to employ some method of management of the fracture other than internal fixation and direct every effort toward obtaining early healing of the wound without infection. Then, if adequate reduction of the fracture has not been maintained, a delayed open reduction and internal fixation through a healed intact skin envelope may be performed. In this connection, however, it must be recognized that an adequately stabilized fracture in good position actually may favor rather than retard wound healing for reasons previously stated. Moreover, with the fracture stabilized in reduction, staged wound care if needed is possible without fear of loss of position.

SUMMARY

The basic principles of the management of open fractures may be epitomized as: (1) proper first aid, such as sterile dressing and effective emergency splinting; (2) immediate correction of physiological deficits to make the patient operable; (3) prompt cleansing and débridement of the wound according to indications in a well-equipped operating room ready for any indicated surgery, not in an emergency room; (4) proper selection of the method of management for the fracture, including, on indications, the use of internal fixation with minimal periosteal stripping; (5) primary suture of the wound only when all factors are favorable, avoiding primary closure when an open wound is preferable as a safeguard against death of skin margins because of excessive tension or for drainage to prevent deep abscess formation, and delayed primary closure by suture (or skin grafts if indicated) of wounds left open if they are clinically clean a few days later; and (6) antibiotics (purposely not mentioned heretofore to place them in proper perspective) administered systemically to prevent invasive infection of living tissue by bacteria presumed to be present in every traumatic open wound. Systemically or locally administered antibiotics or their combination will not prevent the septic decomposition of dead and devitalized tissue in a wound and will not neutralize the necrotizing enzymes in undrained pus. They cannot be used as a substitute for thorough débridement of the wound of an open fracture.

MANAGEMENT OF INJURIES TO THE THORAX

Brian Blades, M.D., Washington, D. C.

Before discussing chest wounds, it is important to emphasize that in cases of major trauma there are usually multiple injuries. No standard textbook patterns are available for study. The surgeon accepting responsibility in the care of the badly injured patient must be versatile and confine neither his interests nor his treatment to one body cavity or region. In all major injuries certain basic factors must be considered and controlled: first, adequate circulating blood volume; and, of equal importance, pulmonary ventilation or open airways, which will result in satisfactory respiration and oxygen exchange.

SUCKING WOUNDS

If the pleura has been penetrated and a sucking wound of the chest produced, it is usually apparent. It is important to remember, however, that if there is any possibility of an opening into the pleural cavity the clothing should be removed, even under the worst conditions, to locate the defect. The importance of prompt closure of sucking wounds of the chest has been repeatedly emphasized. Large sucking wounds of the chest are more dangerous than small defects, but the immediate consequences will depend largely upon the vital capacity of the injured man. In elderly debilitated patients, a small wound may be fatal, whereas, in a young man with an excellent vital capacity, tolerations for amazingly large wounds are sometimes encountered. Closure of a sucking wound will depend upon the conditions and materials available. Occlusive dressings may be employed under emergency conditions. It is important to emphasize that the dressing should be placed over the wound and not packed into the pleura. Once operating room

facilities are available, the wound should be débrided if necessary and closure accomplished.

Shock in thoracic wounds may be the result of either decreased circulating blood volume or impaired pulmonary ventilation and frequently a combination of both. The accepted treatment for shock after injury may be applied in patients with chest trauma, but it is important to emphasize that, if the trachea and major bronchi contain accumulations of blood or mucus, pulmonary ventilation may be seriously impaired. Removal of these secretions by catheter suction, bronchoscopy, or, in serious cases, through a tracheotomy tube, often results in the dramatic improvement in the patient's condition. In the initial evaluation of a patient with a serious chest wound it would be easy to overload the circulatory system in the treatment of shock, when improvement of pulmonary ventilation is all that is necessary.

ATELECTASIS

Complete or partial loss of the cough reflex caused by pain or shock may result in accumulations of blood and mucus in a bronchi, causing atelectasis. The lesions may vary from a complete atelectasis of an entire lung to the involvement of one or more pulmonary segments. Relief of pain, urging the patient to cough, and early ambulation are valuable preventive measures, and, if atelectasis is present, aspiration of the tracheobronchial tree must be done promptly. Sometimes the passage of a catheter into the trachea and application of suction will relieve the condition. Direct visualization through the bronchoscope may be necessary to remove the obstructing material. Massive hemorrhage into the lung or pulmonary edema may produce an extremely serious situation and is best treated by oxygen therapy after the tracheobronchial tree has been cleared. The physiological effects of shock with acute hemorrhage are characterized by fall in blood pressure, increased pulse, slow circulation, and loss of blood volume. If anoxia persists, increased capillary endothelial permeability, with tissue and pulmonary edema, eventually results in death if not corrected.

INJURIES TO THE CHEST WALL

Except in instances of extensive destruction to the chest wall, the most important immediate effect is pain and the associated splinting of the thorax with serious effects on the mechanics of respiration. In minor injuries to the chest wall, the application of adhesive to minimize respiratory excursions may be helpful. A 3 or 4 in. band of adhesive completely encircling the lower costal margin is the most efficient type of strapping. This results in partial immobilization of the entire bony thoracic cage, but it is dangerous in the seriously injured patient because vital capacity will be further reduced. The general use of regional nerve blocking for control of pain has practically eliminated the need for strapping the thorax after rib fractures. Procaine injected either at the site of the rib fracture or, preferably, by the paravertebral route is usually successful in controlling chest wall pain. Long-acting drugs with oil bases have been employed but may be dangerous and are not recommended. Recently, at the George Washington University Hospital School of Medicine experiments have been conducted with hydrocortisone; however, not enough experience has been gained to evaluate this agent.

Trauma to the anterior chest wall and sternum, common in automobile accidents, may result in multiple rib fractures, fracture of the sternum, and fracture of the posterior ribs or the transverse processes that act as fulcrums. This type of injury may cause serious and even fatal consequences. Moreover, after such a severe wound, there are usually associated visceral injuries. Various types of traction have been applied on the sternum to relieve this condition. Towel clips may be placed into the bone and traction applied to a frame with rubber bands or other mechanical methods.

The work of Carter and Giuseffi [1] on the importance of tracheostomy in severe chest wounds has practically eliminated the need for traction, except in extraordinarily severe instances of stove-in chests. The tracheostomy not only makes it easy to remove accumulated secretions from the trachea and bronchi but, more important, reduces the dead space of the upper airway by about 150 cc. An increase in tidal air for the critically ill or moribund patient, made possible by this technique, may be lifesaving. Finally, decreased resistance given by the tracheostomy tube will reduce the high negativity of the intrapleural pressures in the patient struggling for breath and relieve the flail action of the chest.

HEMORRHAGE, HEMOTHORAX, AND PNEUMOTHORAX

By far the most common source of hemorrhage in chest injuries is from the lungs, producing hemothorax. It is important, however, to remember the possibilities of bleeding from vessels in the chest wall. This may occur in either penetrating or nonpenetrating wounds. Bleeding from intercostal vessels in a nonpenetrating wound is extremely rare unless there are multiple severe rib fractures. Bleeding from the internal mammary arteries is almost always in connection with penetrating wounds. The points of entrance and exit of a missile or knife may give some clue concerning the source of bleeding from the chest wall. If there is reason to believe the internal mammary vessels have been injured, exploration should be undertaken unless the patient's general condition precludes any type of surgical intervention. Complete division of an intercostal vessel is usually followed by retraction of the ends of the vessel into muscle and stopping of bleeding. In instances of incomplete division, however, movements of respiration make clotting difficult and bleeding rarely ceases spontaneously.

Hemorrhage from the lung tissue may result from tears in either pulmonary arterial or venous systems. Since the pressures in the pulmonary system are low (in the order of 20 mm. Hg), fatal hemorrhage is uncommon except in extensive wounds involving major pulmonary vessels. In a great majority of serious thoracic wounds, hemothorax will be present. If there has been considerable loss of blood, in addition to the effects of the hemorrhage there will be respiratory embarassment caused by the partial collapse of the lung or lungs, and in extreme cases shift of the mediastinum. The need for emergency thoracentesis can usually be determined by clinical manifestations. Enough blood should be removed to relieve dyspnea, and after the patient's condition is stabilized the systematic evacuation of the hemothorax must be undertaken. The blood should be evacuated early without air replacement so that the pleural space may be occupied by the reexpanded lung. Failure to observe these principles will often result in formation of a chronic hemothorax requiring open operation and decortication. Moreover, the entire pleural space in the untreated case of hemothorax becomes vulnerable to infection.

[1] Carter, B. N., and Giuseffi, J.: Tracheotomy, a Useful Procedure in Thoracic Surgery, with Particular Reference to Its Employment in Crushing Injuries of the Thorax, J. Thoracic Surg. 21:495, 1951.

Small lacerations in lung parenchyma will often seal themselves and a tension pneumothorax will not develop. The seriousness and extent of the pneumothorax will depend, therefore, upon the size of the bronchi injured. If a ball valve action results at the site of the injury and air enters the pleura and cannot escape, a tension pneumothorax may be rapidly fatal. In emergency situations, aspiration with a syringe and needle should be carried out, and, if the pneumothorax persists, catheter drainage and the water seal attachment should be accomplished as soon as possible. If proper decompression is done even large defects will heal, usually spontaneously, and it is rarely necessary to perform an open thoracotomy for relief of pneumothorax.

FRACTURES OF TRACHEA OR BRONCHI AND EMPHYSEMA

The possibility of a fracture of a bronchus or even the trachea should be considered in all cases of severe pneumothorax associated with emphysema. The division of these structures may be complete or partial. Survival from this type of injury is more common in the young, since in older subjects associated injuries to the major vessels and viscera usually result in a fatal outcome. The following findings suggest the possibility of a fracture of a major bronchus: a tension pneumothorax with associated subcutaneous emphysema and mediastinal emphysema (there is often little or no evidence of associated fractures of ribs and a minimal hemothorax considering the gravity of the wound); and, finally, atelectasis of the lobe or lung in connection with the tension pneumothorax. After relief of the pneumothorax, with persistence of atelectasis of the lung or lobe, a tentative diagnosis of a fracture of a bronchus is justifiable and open operation should be performed as soon as the patient's condition will permit it.

Subcutaneous emphysema may result from penetration of the lung by fractured ribs or in patients with tension pneumothorax and injury to the chest wall, allowing the air to take the line of least resistance into the tissues of the chest wall and particularly the subcutaneous tissues. Dissection of air may continue into the neck, face, and sometimes over the entire body. Under these circumstances, the patient has an unpleasant appearance, but his life is rarely endangered and after several days or weeks the air will be absorbed. Emphysema becomes dangerous, however, if there is invasion of the mediastinum causing mediastinal tamponade. Voice changes and difficulty in swallowing are certain indications of severe mediastinal emphysema. Subcutaneous emphysema usually requires no treatment. If there has been a tear of a large bronchus or severe mediastinal emphysema is present, repair of the bronchus or trachea should be performed if the site of the injury can be reasonably localized. If this is not the case, and particularly if the patient's condition is precarious, a cervical mediastinotomy to allow some of the air to escape may be lifesaving.

WOUNDS OF THE HEART

Severe nonpenetrating wounds may injure the heart and cause bleeding into the pericardium. Usually, however, heart wounds amenable to surgery are the result of stab wounds caused by ice picks, knives, and other small weapons. Bullet wounds of the heart are almost always fatal, particularly the through and through variety. The possibility of cardiac damage should be considered in every patient with a wound near or over the heart. It is important to determine, if possible, the instrument that caused the wound, the length of the weapon, and the direction of the stab or missile.

The immediate consequence of heart wounds in patients who survive the original wound is the production of cardiac tamponade. Classic manifestations of cardiac tamponade are a weak, feeble pulse, decreased systolic blood pressure, increased venous pressure, and narrowing of the pulse pressure. Heart sounds are absent or diminished. A roentgenogram of the chest is not helpful, but examination with the fluoroscope will establish the extent of cardiac pulsation. Blood pressure, pulse pressure, and the pulse should be reviewed at 15 minute intervals in every patient in whom there is a possibility of cardiac damage.

It is important to emphasize that in patients with heart wounds there may be an initial period of shock and unconsciousness followed by a lucid interval. During this period the victim may give the impression of being intoxicated, and if he has been drinking it is easy to attribute his condition to alcoholism. As the tamponade increases, a second period of unconsciousness will occur, and, if blood is not removed from the pericardium, death will follow shortly. There are differences of opinion concerning the management of traumatic hemopericardium. Until rather recently, most surgeons insisted on immediate operation and suture of the wound. Blalock and Ravitch [2] have advocated initial aspiration of blood from the pericardium to relieve the tamponade and postpone open operation until it is evident that there is continued bleeding. Probably the choice of conservative or radical approach is not so important as the early recognition of the condition. Even if a conservative program of aspirating the pericardium once or twice before resorting to open operation is selected, preparation should always be made for thoracotomy and the aspirations performed in the operating room.

SUMMARY

The basic principles in the management of thoracic wounds consist of maintenance of adequate circulating blood volume and open airways to insure satisfactory pulmonary ventilation and oxygen exchange. The possibility of severe visceral injury in all patients having chest wounds must be considered and existence of such injury established or ruled out. Tracheostomy is an important adjunct in the management of all severe ventilatory and respiratory problems.

PRIMARY CARE OF INJURIES ABOUT THE FACE

Truman G. Blocker Jr., M.D., Galveston, Texas

The primary care of acute injuries of the face usually falls to the lot of the general practitioner or to the hospital house staff on emergency room call except in industrial areas where traumatic surgery has become a specialty. The technique of repair of the majority of lacerations that do not involve actual loss of tissue can be acquired by any conscientious physician without formal specialized training, and beautiful cosmetic results may be obtained by adherence to a few basic reparative surgery principles. On the other hand, mistakes made through carelessness, ignorance, or haste often result in cicatricial and contour deformities that require secondary definitive procedures and can perhaps never be eradicated completely. The unfortunate results of using coarse suture material with big "bites" taking in the skin and deeper structures with each stitch; of wound disruption from hematoma formation; and of lop-sided faces, misplaced eyebrows, and crooked mouths and noses from lack of attention to the symmetry of the features and from failure to observe the anatomic pull of the tissues in motion are not uncommon.

The first consideration in patients with injuries of the head and neck should be the maintenance of an adequate airway. First-aid workers should be taught to keep them in an upright position or carry them prone on a stretcher. Foreign material should be removed from the mouth. A gauze pack applied to the face will control hemorrhage in the majority of instances; a Barton's bandage may be applied if the distance to a hospital is great. The use of a nasopharyngeal airway often obviates the necessity for performing a tracheotomy, but a set should be kept at hand for patients with extensive fractures, with injuries to the floor of the mouth and the neck, and with respiratory tract burns. While appropriate measures are in progress for the treatment of shock, hemostasis of major bleeding points should be obtained. An estimate should be made of concomitant injuries and a second surgical team provided if necessary and obtainable. Work on the face itself must be unhurried and deliberate.

Traumatic lesions are too often approached as surface lacerations with obligatory requirements for surgery. If they are considered first as diagnostic problems and evaluated according to the ultimate functional and cosmetic prospects, elective elements enter into the plan of repair. Conservative débridement and primary closure are important rules for injuries about the face even with war wounds and following other heavy contamination. For this reason, especially thorough mechanical cleansing with detergents and saline solution should be carried out after local or regional anesthesia. Antibiotics should be given immediately upon admission and for several days postoperatively, and tetanus inoculation must never be omitted. No antiseptics should be used in the wound itself. Clots, loose tissue, and débris should be flushed out, but only tissue that is definitely devitalized should be cut away. Small bone fragments in areas of comminuted fractures are left undisturbed if possible. If fascia is greatly involved, it should be incised in the direction of its fibers for the entire extent of the skin wound, and the involved portion should be removed. Decision with regard to muscle débridement may be made on the basis of its consistency, contractibility, and ability to bleed; studies made during the Korean war have shown that these tests are more reliable than color and apparent necrosis.

Examination of the face for concealed fractures may be made conveniently and accurately even in the presence of considerable edema by palpating for displacement on each side in three areas: first, around each orbital rim; second, along the lateral surface of the zygomatic arch and the superior border of the zygoma; and third, along the inferior border of the zygoma and the lateral surface of the maxillary sinus. If the underlying bones in these areas are symmetrical and intact, if there is no obvious deformity of the nose, and if the teeth are in occlusion, the examiner may rest assured that there are no major fractures of the face. Soft tissue wounds must be carefully examined at all depths for injury to major vessels and nerves; perforation into the oral, nasal, orbital, and sinus cavities; and damage to such structures as the parotid duct and nasolacrimal apparatus.

Often at first glance it is difficult to select a point of reference in suturing major lesions of the face. The eyebrow, which should never be shaved, the eyelids, the alas of the nose, and the vermilion border of the lips will serve as guides, and a few temporary tacking sutures may be inserted for preliminary orientation. These structures must be reconstructed carefully in both horizontal and vertical planes for restoration of the symmetry of the individual features and of the face as a whole.

To achieve minimal scarring it is necessary to eliminate dead space by accurate approximation of the tissues in layers and to close the deeper layers shorter than the superficial ones. Tension in the skin must be avoided by undermining in the area adjacent to the injury and by revision of the wound so that suture lines will fall in directions that are anatomically "correct." Linear contractures and notching in lacerations that fall across the normal wrinkles of the face or that cross the margins of the nose, lip, and eyelid may be prevented by staggering the closing incision. In the neck vertical lesions should be closed with a plastic relaxing operation to prevent scar hypertrophy or puckering. This technique, frequently employed in definitive reconstructive procedures, also may be used elsewhere when undermining alone does not achieve sufficient relaxation of the tissues along the central line of tension. Here two triangular flaps are outlined with a common side. The arms of the Z, or reversed Z, as the case may be, are usually placed at an angle of 60 degrees, and the flaps are transposed.

Professor of Plastic and Maxillofacial Surgery, the University of Texas Medical Branch.

Read before the Joint Meeting of the Section on Military Medicine and the Section on Surgery, General and Abdominal, at the 104th Annual Meeting of the American Medical Association, Atlantic City, June 9, 1955.

The tips are blunted to avoid compromise of the circulation. Lesions of the cheek result in exposed scars unless they are situated close enough to the hairline, the lower eyelid, the jaw margin, the nose, or the nasolabial creases to be camouflaged in these locations. In the central portion of the cheek, however, zig-zagging of the suture lines will make it less noticeable, since all portions of the scar will not catch the light at once.

CARE OF VARIOUS FACIAL LESIONS

Fine suture material should be employed in lesions of the face, and the stitches should be placed close together. Our individual preference is for wire, which causes practically no tissue reaction. For the deep layers one or more removable continuous 36 wire is used and for the skin 000000 silk, with interrupted stitches placed so that the line of healing will be slightly raised. As a general routine we employ large, bulky dressings to maintain firm, even pressure for a period of three or four days. We begin to remove skin sutures in 48 hours but leave the pull-out wire in place for 7 to 10 days.

Avulsion Wounds.—In avulsion wounds, where skin and soft tissue have been lost, better definitive results will be obtained if raw surfaces can be eliminated by sewing of the skin to the mucous membrane, as in lesions about the mouth, cheek, and nose, by the use of a rotational flap; or by a temporary thick-split graft. Exposed bone should be covered by adjacent soft tissue, but on no account should closure be made over open sinuses unless adequate drainage into the nose can be accomplished or unless a portion of the upper alveolar process has been lost so that drainage occurs into the mouth. If it appears best to leave the wound open for secondary closure, a few deep sutures may be indicated to make the later problem less complex after induration of the tissues has occurred. At any rate, the wound should never be packed open with a mass of gauze so that drainage is obstructed.

Mouth Lesions.—In lesions about the mouth care must be taken to suture lacerations of the mucosa and to follow surgery with frequent irrigations and other measures to improve oral hygiene. If facial trauma has been extensive, patients should be fed by an indwelling plastic tube to give better immobilization of injured parts and to prevent the accumulation of food particles in the mouth.

Facial Burns.—Burns of the face should be treated by mechanical cleansing initially with débridement of loose shreds of tissue only. The exposure method of handling we believe to be the procedure of choice unless lacerations are also present. Dressings are absolutely contraindicated in the treatment of frostbite. Chemical burns of the eye require immediate priority over other types of injuries and must be washed as soon as possible with copious amounts of whatever innocuous fluid is at hand, followed by administration of local antibiotics and mydriatic drugs for pain. Phosphorus burns in the Korean war were treated by removal of particles of the chemical, neutralization with copper sulfate, and washing with saline solution. Patients with ocular injuries should be seen as soon as possible by an ophthalmologist, with the eyes bandaged meanwhile. If the injury is such that the cornea is exposed, the lid conjunctiva must be reconstructed to prevent permanent damage.

Suturing of Face Lacerations.—Every attempt should be made at primary suture of face lacerations within 4 hours after injury, or at least 12 hours. In considering the possibilities of mass casualties, in the event of nuclear warfare, it is obvious, nevertheless, that delayed closure would have to be carried out in the majority of instances. First priority in head and neck injuries would be given to coverage of exposed brain, eye injuries, respiratory obstruction, shock, and uncontrollable hemorrhage. Attempts should be made as soon as possible in facial trauma, after institution of shock measures, to cleanse wounds mechanically and to apply a few strategically placed sutures, matching tissues and effecting partial closure at least. Maxillofacial patients must not be allowed to lie on their backs meanwhile but should be sitting or lying with the face down or to the side.

Nose Fractures.—Fractures of the nose may usually be treated by molding and immobilization with an intranasal pack associated with an extranasal splint. If, however, the bridge has been driven back between the maxillas, forward traction must be applied, for which a pin through the nasal bones may be required. Simple malar depressions and depressions of the floor of the orbit may be approached through the mouth and kept in place by packing of the maxillary antrum for several days with iodoform or BIPP (bismuth iodoform paraffin paste) gauze. Depressions of the zygoma are reached through a small incision just inside the hairline, with a malar elevator passed between the temporal muscle and fascia. Fractures of the outer orbital rim may require direct wiring.

Jaw Fractures.—Fractures of the jaw should be treated initially by immobilization with simple devices employing elastic traction. If sufficient teeth are present, we prefer the Stout intramaxillary multiple-loop wiring with intermaxillary elastic bands for reduction and fixation. Other workers employ labial arch bars of metal or acrylic wired to the teeth in combination with intermaxillary elastic traction. During transportation and until early nausea and vomiting have subsided, only a few bands should be used, and rigid intermaxillary fixation should never be used during this period. For fractures in edentulous jaws intraoral splints of one type or another are applied. These, and the more complicated fractures of the mandible and maxilla involving extensive displacement or loss of bone, require as a rule the technical assistance of the maxillofacial or oral surgeon for definitive treatment.

SUMMARY

The proper primary care of facial injuries should follow certain general principles: (1) maintenance of adequate airway; (2) careful hemostasis; (3) diagnosis of injury to soft tissue and supportive structures; (4) prevention of infection by thorough mechanical cleansing and conservative débridement, systemic antibiotic and tetanus therapy, closure of "dead spaces," and prevention of hematoma formation; (5) accurate replacement of tissues by approximation in layers and by attention to the vertical and horizontal symmetry of the features and of the face as a whole; (6) minimal scarring by use of delicate suture material, undermining of the skin for re-

laxation in closure, revision of incisions as required to avoid contractures and notching and hypertrophy, and application of bulky pressure dressings to prevent excessive edema and provide immobilization; (7) elimination of raw surfaces in avulsion wounds in preparation for definitive surgery and partial closure whenever possible; and (8) simple primary reduction of uncomplicated fractures of the facial bones. The social, economic, and psychological implications of facial trauma are self-evident. Results obtained by careful attention to detail at the time of primary treatment are well worth the extra time and effort that these lesions require.

A PLAN TO MAKE AVAILABLE MORE BLOOD IN CASE OF WAR OR DISASTER

Lieut. Col. Joseph H. Akeroyd (MSC), U. S. Army (Res.)
and
Lieut. Col. William H. Crosby (MC), U. S. Army

Blood transfusion for the treatment of severe injury grew up and came of age in wartime, and methods of providing and using large quantities of stored blood for the care of mass casualties were painfully developed by the armed forces of the United States and other countries. In World War II the British Army established a transfusion service in support of their forces in North Africa, and the U. S. Army organized a similar service in Italy. Both of these systems were self-sufficient with regard to donors. It was not until 1944, after the invasion of northern Europe, that blood collected in the United States was flown into the combat zone. Meanwhile an important change had taken place: the surgeons in the combat zone had learned to use blood and to rely on it in the treatment of severely wounded battle casualties. In North Africa one unit of whole blood had been utilized for every 10 men wounded in action. By 1945 one unit was used for every two men wounded in action. The Korean War showed a further increase: one unit of whole blood was used for every man wounded in action. These, of course, are average figures: 80% of the wounded received no blood at all, and some men received as many as 50 units. In Korea blood was provided somewhat in excess of need, so that it was always available, and it was often administered where plasma or a substitute might have sufficed. Blood for the combat zone in Korea was obtained in the United States and to some extent from American troops in Japan. It was provided in unstinting amount. For the transfusion service, this was a lush time. We may never again "have it so good." Not only was the quantity adequate but the quality was first-rate. The blood was reasonably fresh, and its safety was guaranteed. This latter and eminently desirable characteristic was attained by making use of universal donor blood.

UNIVERSAL DONOR SYSTEM IN KOREAN WAR

The universal donor system has a great deal to commend it. The donors are all of group O; hence there are no A or B antigens on their red blood cells and they may be transfused without being hemolyzed by the recipient's anti-A (or anti-B) antibodies. The donor's plasma may be dangerous: the anti-A (or anti-B) antibodies, if present in high titer, may injure the red blood cells of group A (or AB and B) recipients, but this danger may be circumvented by eliminating from the universal donor transfusion service blood of all donors who have high titers of antibodies. This was done during the Korean war. It resulted in the elimination of 10 to 35% of our universal donors. In all probability, not all of those eliminated were dangerous universal donors, but, since there were ample donors, we could afford to screen out any who were even suspicious.

The determination of the blood group and the tests for safe universal donor blood were performed in laboratories in the United States and Tokyo, well away from the combat zone where the blood was to be used. All of the blood shipped into the combat zone was safe universal donor blood and, so far as A and B blood group antigens were concerned, was compatible with any recipient. Thus, the people in the field who used the blood were relieved of the responsibility of assuring that transfusions were compatible. Transfusions in the combat zone were begun without typing and cross matching, and there were no recorded incompatible transfusion reactions due to universal donor blood. This was an enormous advantage. Transfusions could be started instantly when a wounded man arrived, whether at a battalion aid station or a mobile surgical hospital. Skilled personnel and equipment for cross matching were not needed, and the probability of error under stress was eliminated. In practice, the universal donor system proved to be an extremely valuable expedient. However, it possesses one serious limitation. It is wasteful of the blood donor panel. It discards all of the blood of group A, B, and AB and that of group O considered dangerous universal donor blood by reason of the high titer of anti-A or anti-B antibodies. This blood of course is not discarded. It is diverted to the plasma program or used in hospitals where typing and cross matching can be done. But it is eliminated from the universal donor system, and this means that the system as it is presently defined can utilize only 30% of the donor panel (see table). This is not a serious limitation when a relatively small combat zone, as in Korea, can be supported by the population and transportation facilities of the United States. But were we to become involved in a larger war,

---

From the Department of Hematology, Army Medical Service Graduate School, Walter Reed Army Medical Center, Washington 12, D. C.

Read before the Joint Meeting of the Section on Military Medicine and the Section on Surgery, General and Abdominal, at the 104th Annual Meeting of the American Medical Association, Atlantic City, June 9, 1955.

The discussion was opened by Commander Mary Sproul and Dr. John G. Gibson.

or a war in several theaters, or a war involving the United States mainland, we could not afford to rely upon a transfusion service as prodigal as the present universal donor system.

DANGERS OF UNIVERSAL DONOR SYSTEM

Our department of hematology has had this problem under investigation for the past two and one-half years. Our first efforts were directed at the dangerous universal donor. It seemed preposterous that 35% of universal donors were dangerous as indicated by the screen employed to identify them. This screen consisted of diluting the donor's serum 1:200 or 1:250 with saline and adding a mixture of group A and B red blood cells. If agglutination occurred, the blood was considered to be dangerous. Experience has demonstrated that this test eliminates dangerous universal donors, but it undoubtedly errs on the side of caution and thereby eliminates a number of safe donors as well. The saline agglutinins, upon which this test is based, are not the dangerous antibodies and therefore there remained a possibility that a dangerous universal donor might slip through the screen. A survey of 85 donors selected at random from a military population confirmed this (see figure). There were donors with low titers of saline agglutinins and high titers of hemolysins and incomplete (albumin) antibodies, which are believed to be the pathogenic ones. But in spite of these apparent loopholes the system in practice proved safe.[1]

Utilization of the Donor Panel

Blood Group	Proportion of American Population *	Proportion Used in Universal Donor System	Proportion Used in Modified System
O	45	30 †	45
A	41	..	41
B	10	..	..
AB	4	..	..
Total	100	30	86

* Snyder, L. H.: Blood Grouping in Relation to Clinical and Legal Medicine, Baltimore, Williams & Wilkins Company, 1929.

† 65% of group O are safe universal donors.

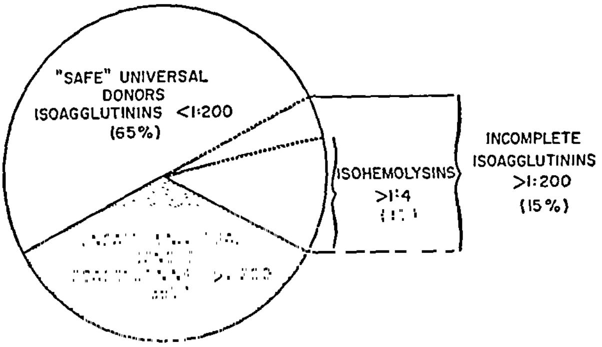
Transfusion experiments, using dangerous plasmas, have suggested that there may exist a further dimension of this problem. The dangerous plasmas may provoke severe transfusion reactions only in certain susceptible recipients. These dangerous recipients may be few in number; if it is so, this unappreciated circumstance may have been an important factor in mitigating the dangers of the universal donor system.

Efforts to find a more selective screening test for universal donors have not been rewarding. Because of the difficulty in identifying dangerous donors by means of plasma transfusions, we have not been able to define them. Efforts to devise other screening tests that would identify high titers of hemolysins or incomplete antibodies have bogged down in techniques that would be unwieldy when applied to the testing of hundreds of units of blood. At the present time, we are unable to suggest any practical means whereby the number of safe universal donors might be increased, unless it be to use Witebsky's soluble blood group specific A and B substance in all blood collected for use in the combat zone. This proposal is under study at the present time.

MODIFICATION OF SYSTEM

Even if we were able to use all universal donors, such a transfusion service would take only 45% of the donor panel and would discard 55%. To find a way out of this unprofitable situation, we have proposed a modification of the universal donor system itself. This suggestion is based upon a plan put to use by Zeitlin in one of the emergency obstetric transfusion services in London.[2] By employing a single blood-typing procedure, this plan permits the use of all group O blood and all group A blood, or more than 85% of the donor panel (see table). The blood of every recipient is mixed with potent anti-A serum. Agglutination of the red blood cells indicates the presence of the A antigen and means that the recipient is of group A or AB. He would receive group A blood. Failure to agglutinate indicates the absence of A antigen. Such a recipient is of group B or group O and would receive group O blood. No further typing or cross matching would be carried out before transfusion was begun. The following statement indicates that a plan similar to that proposed here has been under consideration by the Federal Civil Defense Administration; it differs in that cross matching is stipulated by the Federal Civil Defense Administration.

> Group-Specific Transfusions. Only blood of group O can be given without crossmatch, and this is strictly an emergency procedure. Transfusions of unmatched group O blood should be abandoned as soon as conditions permit to conserve blood for group O recipients. Donor blood of the other groups must always be crossmatched with blood from the recipient before administration.
>
> Donor blood of the recipient's blood group should be selected and the two should be carefully crossmatched with a technique which will reveal both blood group and Rh incompatibilities.



Distribution of isoantibodies in 81 universal donors.

> Although Rh negative blood can be given safely to Rh positive persons, the supply will be limited and should be reserved for Rh negative patients.
>
> During the transitional phase, and when limited blood grouping and matching facilities are becoming available, it may be desirable as a first step to expand collection of blood to include group A in addition to group O donors. Group O blood can then be crossmatched for group O and group B recipients, and group A blood for group A and AB recipients. It is important that the major side of the crossmatch (donor cells and recipient serum) be double-checked for compatibility when cells of different groups are matched.[3]

3. U. S. Civil Defense: Blood and Blood Derivatives Program, revised edition, Federal Civil Defense Administration, 1953, p. 159.

IMPORTANT PRECAUTIONS FOR NEW SYSTEM

The plan considered here is not without certain soft spots, and we must be certain that these areas of concern are not unreasonably dangerous. Recipients in group B would still be threatened by dangerous levels of anti-B in the plasma of group O blood, just as recipients in group AB would be threatened by the anti-B in the plasma of A blood. It seems fairly clear that the anti-B problem is not nearly so dangerous as anti-A, and it may be diminished to insignificance by the use of blood group specific substances. The anti-A typing serum must be avid, accurate, and exceptionally rapid. It must be able to distinguish weakly reacting A's quickly and unmistakably. Agglutination must develop within a matter of seconds so that harried technicians will not be tempted to set the test aside for later reading. Dr. L. K. Diamond and Dr. Ernest Witebsky have assured us that such serums have been developed and adequate amounts can be produced. Field trials of these serums are under way at the present time.

Perhaps the most critical factor is the ability of the personnel who must administer the blood. During the Korean war, the universal donor system required little or no knowledge of blood transfusion where one sort of blood was used for all recipients. Most of the transfusion reactions that were recorded in Korea occurred when attempts were made to use cross matched blood that was locally procured.[4] The proposed modification requires no high level of skill, but it certainly requires a high level of conscientiousness and a lively knowledge of the dangers and disastrous consequences of error. The personnel of the transfusion service must know how to perform the anti-A test. They must know how to interpret it. They must be certain that it is always a person with A antigen in his red blood cells who receives A blood. This will require a higher level of training and awareness in the personnel of the transfusion service at the level of the mobile surgical hospital.

With regard to the training of these personnel, we are convinced that we should set our sights even higher than the requirement of this modified universal donor system. If ground warfare in future wars is more open, more insular, there well may be times when the mobile surgical hospital or its equivalent must procure its own blood. The level of training of the transfusion team should permit this with a reasonable assurance of its safety. Training schedules to meet these requirements have been constructed and the training cycle has actually been completed on "guinea pigs" at the Army Medical Service Graduate School. It is hoped that within the year we may be able to submit the system to a complete field trial during one of the large-scale maneuvers.

The surgeon general of the Army has sought the advice of the National Research Council concerning this modification of the transfusion service in the combat zone. The matter was referred to the Subcommittee on Blood and Related Problems, which gave the proposal a qualified approval and encouraged further study in the field. During the discussion, Dr. L. K. Diamond stated that the planners for civilian defense in the Boston area had been scrutinizing this scheme for some years. He said that, should war come to the United States mainland, the civilian medical support of disaster areas must use an emergency transfusion service of the univers donor variety, not limited to the 30% of safe univers donor blood. "There may be disadvantages to the d vice of anti-A testing, but there is no other way."

SUMMARY

Review of the universal donor blood transfusion sy tem as it was employed in World War II and the Kore war reveals that the chief disadvantage is that it utiliz only 25% of the available donor panel, a limiting fact that would seriously impede the transfusion service any large-scale war or civilian disaster. A modificati that would permit the use of all group O and all group blood, or 85% of the donor panel, also has certa limitations that seem not impossible to overcon Through the cooperation of military and civilian inves gators, the obstacles to this modified universal don transfusion system may soon be reduced.

Explosive Risks in Surgery.—Explosive risks associated w surgery can be divided into four groups: the presence of infla mable anesthetic gases or vapours; eructation by patients suff ing from pyloric stenosis; collections of gas in the lower bov and the generation of inflammable gases during electro-coagu tion or diathermy of the body tissues. Taking this last risk fi it has been proved that the gases given off when high-freque currents are applied through a fine electrode to body tissues c tain acetylene, ethylene, carbon monoxide, and hydrogen varying quantities. Fortunately these are usually ignited as t are formed and their combustion contributes largely towa the spluttering associated with diathermy. If, however, t collect in a confined space such as the mouth, rectum or blad they may accumulate sufficiently to form an explosive mixtu This undoubtedly is the cause of those occasional pops he during fulguration of bladder growths, for the gases can escape and rise to mix with the air bubble and, upon occasi the electrode may set up a spark near them and cause a mild a muffled explosion. Similar types of explosions have occurred the mouth while using diathermy upon the tongue in cases wh no inflammable anesthetic was in use. It is not beyond realms of possibility therefore that diathermy gases could cumulate within the lumen of a sigmoidoscope and, mixing w the air within that instrument, be ignited by a spark caused wh next the diathermy was used . . . Normally there is little oxyg within the bowels to support combustion, but when perista is brisk, as it is with some anaesthetics (particularly spinal ana thesia) swallowed air or oxygen from an anaesthetic mixture oxygen excreted into the lumen of the bowel from the blo stream, may reach the rectum in less than thirty minutes. Wh operating through a speculum or sigmoidoscope, of course, is admitted to the lumen of the instrument and will be prese to support combustion if suitable ignition is supplied. Seve cases of explosions during minor procedures within the lar bowel have been reported . . . . As an anaesthetist I should li to draw attention to the fact that none of the reported cas was receiving an inhalation anaesthetic . . . . Several suggestio have been made regarding the avoidance of such accidents . . . The diet should be regulated for some days with a view to avoi ing meteorism . . . . Smoke for electrodissection should cleared in some way in case it accumulates and forms an e plosive mixture with air introduced through the operati endoscope. The best suggestion which has been put forward that a steady flow of some inert gas should be introduced to th far end of the endoscope through a fine catheter, so that an gases introduced from the bowel are steadily swept out of th instrument. In addition this will also displace any air whic might otherwise support combustion.—A. H. Galley, M.D., E plosive Risks in Large Bowel Surgery, *Proceedings of the Roy Society of Medicine*, July, 1955.

PSYCHOLOGICAL REACTIONS IN MASS CASUALTIES

Elmer L. Caveny, M.D., Birmingham, Ala.

Americans rarely panic as a result of a major disaster. It is realized that this statement has been made on a number of occasions by individuals of varying prominence in the field of disaster research and is again made here, as always, without substantial support. In like manner, it has been repeatedly implied that Americans are more likely to turn to tremendous reserves of courage, generosity, and heroism in times of disaster than to panic. Such statements are indeed comforting and encouraging and possibly true but, unfortunately, are based on studies involving isolated incidents such as tornadoes, air crashes, large fires, and alarming radio broadcasts, which fail to reveal the entire situation. The condition for studying the reactions of the American people during a disaster, as that arising from an atomic attack, has never presented itself—we trust that such will never be. Tentatively, the conclusion is that the American performs much better when confronted with a specific situation than in anticipation of an abstract future event; that regardless of how emotionally shocking the situation may be, if he has something to do rather than to contemplate, his actions are much more likely to be controlled and purposeful.

Not too much reliance can be placed on the numerous attempts through psychological theory to predict with any degree of accuracy what will happen in the event of an atomic disaster and how we, as Americans, will respond. Dynamic psychology is a very young and incomplete science and is easily strained beyond its limited control of information as to what is taking place in an atmosphere of situationally rather than neurotically aroused anxiety. Our shores and homeland have never been invaded by the devastating weapons of modern war. We know something of the psychological reaction of the American male in stressful situations, even those caused by the horrible destruction of atomic and thermonuclear weapons with the resulting mass casualties—but only as he reacts to them on foreign shores, not in his own backyard. What the actual effect would be upon the civilian population in the event of a sudden atomic attack is open to considerable speculation. In all probability there would be widespread panic, the degree depending entirely on the state of preparedness of the civilian population.

APPROACHES TO PREPAREDNESS

Preparedness embraces two principal themes of approach; the first is that of mental health as it affects the individual as well as the group and is by necessity a long-range educational undertaking. It is generally accepted that stress accruing from threatening situations is based largely on the way the affected person perceives it and depends on many factors, including the individual's genetic equipment, basic needs and longings, earlier conditioning influences, and a multitude of life experiences and cultural pressures.[1] The second theme of approach is that of civil defense, which involves a host of undertakings. These two themes in disaster preparedness are uniquely capable of greatly aiding and benefiting each other in accomplishing their respective tremendous tasks in the years ahead.

Much has been written on civil defense during recent years, and the degree of attention paid to these writings varies with the perceived imminence of attack. The word apathy is appearing with more frequency in reports on current civil defense programs.[2] Since civil defense is geared to hazards of war, it is difficult to maintain the interest of the citizenry in projected situations of a "tomorrow" that never comes. The existence of this state of affairs is of much concern to those in positions of responsibility for safeguarding the civilian population. It has been suggested that by giving serious consideration to certain concepts relating to mental health in its current enthusiastic nationwide program, the civil defense program may, in turn, be brought more in line with daily living experiences.[3] Preparedness for the emotional aspects of disaster is of the same long-range pattern as is the preparedness for the inevitable crisis of everyday living. The community that has a well-organized mental health program in its schools, churches, and other activities is struggling to combat obstinancy and lessen tensions. There is a sinister relationship between the mental health problems involving present-day living and the psycological tensions being created throughout the world by dictatorships. Hoffman [4] states: ". . . To most of us war's aim and end is victory on the field. But to the Kremlin military action is but the most visible and spectacular zone of combat in an unremitting war against the free world. Herein lies our strange and new and often hidden danger—a danger that we cannot fend off by arms alone. We must know that for the Kremlin the military is only one of four fronts—each a battleground of implacable attack. These four fronts are the military, economic, political, and psychological."

In civil defense preparedness there are certain long-range psychological goals that must be emphasized in addition to the acute emergency phases. Communities with well-operating mental health programs are better prepared to accept sudden change and emotional shock than the ones that do not have them; thus, an interest in and forwarding of the existing mental health activity of a community is an imperative prerequisite of a civil defense program that takes into consideration the emo-

tional needs of people during a disaster.[5] In addition, such a procedure is a means of maintaining the interest of the citizenry in civil defense activity, in that the mental health program is directly involved with human interest events of daily living.

The nation, today, is called upon to play a vast number of unfamiliar roles and to create strange new parts for practically everyone. The American people are not accustomed to the ever-present possibility of being attacked on their homeland nor to being continuously involved in defensive and offensive alliances. The Americans do not know how to deal with their own power, nor how to appraise their own insecurity, much less to feel comfortable in the role of being constantly held responsible for the preservation of world peace.[6] Whether they are appropriately used or inappropriately used, adaptive and protective mechanisms operate only in relation to the present, in a manner determined by the past, and often with dangerous consequences for the future.[7] Psychological teaching of recent years has frequently pointed out that the studies of man as a growing, living, and social organism are producing a wealth of information that may bring about changes not only in the condition of human life but also in the social and personal characteristics of the individual himself. Such a situation has never been closer to reality than in this atomic era.

A well-organized disaster plan should not include the technique of crying havoc as an incentive to rational thinking. Culturally engendered anxiety and the methods of resolution become formalized, and it is quite possible the anxiety and tension ceases to be operative long before the tension-producing factors lose their potency. Still, there is probably too much emphasis on "panic" as a magic word.[8] It is unlikely that the American people would ever be frightened into a better state of preparedness, even though it is quite possible that casualties may be greater by reason of panic than as a result of the disaster itself. A population that is well-prepared, and has good morale and leadership, will still have a large percentage of the people temporarily overcome by fear. The degree and duration of that fear, as well as the prevention of mass panic itself, will depend in large measure on the level of mental health and efficiency of the civil defense system. The basic and foremost objective of that system is to establish within the American people, with assuredness, the desire and capacity to remain calm and orderly in the face of atomic catastrophy.

The fact that we cannot foretell what would be the psychological reactions of the American people in case of an atomic disaster is all the more reason intensive research and study should be continued in this realm. We might well approach this particular subject as we do the buying of fire insurance on our homes—hoping we will never need it, but fearing that we might! Whatever might be contributed toward psychological preparation for a major disaster is just that additional fire-fighting equipment and fire insurance at a lower premium.

UNDERSTANDING HUMAN EMOTIONS

Many of us are making it our common cause to understand more completely the nature of human emotions and emotional disorders as they are found in mental health and mental illness in the various economic, social, and occupational classes. Tyhurst [9] has pointed out the importance of determining how these classes of Americans would react to situations of community disaster and personal stress. To do this, we must come to a more common basis of understanding as to methodology and aims. There are certain fundamental and puzzling questions that concern us [7] such as: what is the nature of the so-called psychic trauma; what mechanisms can the neurophysiologist, the endocrinologist, and the experimental biologist discover to account for the residuals of intolerable stress imposed upon the immature organism, remaining as scars upon the personality perhaps for the duration of life; and how is it possible for the mother to shield her offspring effectively against these otherwise mentally injurious environmental stresses?

From their beginning, the two traditions of research originating in the classic studies of Cannon and Pavlov on the one hand, and of Freud on the other, have converged upon the same fundamental problem; namely, the fundamental significance of emotion. This is of considerable concern in facing the problem of the meaning of operational psychic trauma. This physiological tradition of Cannon and this psychodynamic tradition of Freud will eventually coalesce in spite of the well-known inertia and conservatism of thinking peculiar to the life sciences. This merger will be hastened when it is recognized that between the organic position and the psychodynamic position, there is another distinct viewpoint—the behavioral or biological position, which, apparently, is steadily gaining in importance.[7]

EFFECTS OF STRESS AND REACTIONS TO IT

Since Cannon's classic studies of the cat's emergency reaction to various stresses, much has appeared in the literature on the physiology of stress. It is not difficult to impose so-called controlled stress upon an organism in the laboratory, but it is extremely difficult or impossible to do so out of the laboratory. When such controlled stress is imposed, however, it is of logical necessity to pursue the organism into its normal living conditions, if the effect of the stress is to be determined for the total biological unit and not just for the isolated organ.

Repeated studies of stress and its effects on human beings have failed consistently to bring forth a satisfactory answer to the much sought-after question of why certain individuals withstand and others succumb to a stressful situation. In the laboratory the stressors commonly employed are such as may most easily be controlled and reproduced; for example, cold, treadmill exercise, electric shock. It is supposed that the organism, reacting as a computing machine, calculates the sum of stressors and reacts to the appropriate intensity. Such a built-in calculator, however, is not present in stressful situations beyond laboratory control, as in actual combat or an atomic disaster. It is then that the inborn instinct of self-preservation comes forth and assumes such duties, the action of which is unique to each individual.

Training and cultural backgrounds develop in an individual relatively fixed ideas of how he is expected to appear, behave, react, and even feel. A person's reactions to what he perceives as dangerous are often out of keeping with his "ideas" of what he "ought" to do.[1] When he is stunned and bewildered, each individual reacts differently to trauma or sudden change in environment.[10] As to the nature of the so-called psychic trauma, it might be considered an injury, wound, shock, or resulting condition. The trauma might well be that which results from the sudden and unexpected bombing of a city. When in an unbearable situation to which the individual is unable to adjust temporarily, he might possibly react by panic. The dangerous situation and the subsequent conflict, which is at best only partly conscious, evokes unwittingly within the person an unsuitable protective reaction. Some will react with withdrawal, become seclusive and noncommunicative; others will react with confusion and marked disorganized behavior; others will respond to the stress in stride and will attempt a constructive resolution to the new situation.

It is the basic function of the mental apparatus to establish equilibrium and stability after a disturbance by external stimuli. The deleterious effect occurs when there is too high an influx of excitement and the individual is unable to discharge it; i. e., it is beyond the limits of his mastery. The limits of mastery in a new situation depend on the constitutional factors and previous experiences of the individual. As has been repeatedly pointed out, previous conditioning and experience will do much in alleviating the possibility of panic and confusion, by greatly aiding the person to master the new situation.

The traumatic effect can be heightened by waiting and anticipating, without a prior knowledge of what to expect, and it seems to be in direct relationship to the unexpectedness of the trauma. If an individual is prepared for a coming event, and has anticipated it in thought through a thorough knowledge of what might occur, he will more likely be able to accept the trauma when it comes and thus be able to overcome and resolve the situation constructively. During the period immediately after the catastrophic event, the individual who has been stunned and bewildered needs to ventilate, which is a child-like attitude of dependency; and to be permitted to do so is an essential adjunct to treatment at this phase. He wants to be given something—coffee, a cigarette, or a blanket; he wants to be looked after. The importance of the giving and nursing is not so much related to the actual kind of act as to the psychological meaning of the being cared for.[9] This dependency is generally transitory, and the individual is quite unwilling to talk about it a day or so later. The state is associated with the need to be with others and a disinclination to be left alone.

GROUP BEHAVIOR

Man, by inborn instinct, is a gregarious being. His entire life is dominated by contact with other people. When confronted by danger, his major drive to be freely accepted as a full-fledged member of the group is intensified. Yet, man's behavior in any group is psychologically different from that when he is alone. He does things as a member of a group that would be completely foreign to him without its influence. This behavior is adequately explained by the basic principles of group psychology.

In the ordinary sense of the word, crowd means a gathering of individuals irrespective of their genetic equipment and backgrounds or whatever chance may have brought them together. Under certain circumstances, and only under those circumstances, a group of men presents new characteristics very different from those of the individuals composing it. Sentiments and ideas of all persons in the gathering take one and the same direction, and the conscious personality of the individual disappears. A compositing of mental reactions and attitudes is formed, in all probability transitory, but presenting clearly defined characteristics. Such a group becomes a "psychological crowd" and forms as a single being. According to Freud,[11] a person in a group is brought under conditions that allow him to throw off the repressions of his unconscious instincts. In a sense, the conscious disappears; the individual develops a sentiment of great power that allows him to give free reign to instincts, that, had he been alone, would have been controlled. He sacrifices his interest to the collective interest.

The absence of community organization, education, principles of mental health, and factual orientation in the situation faced may add immeasurably to the impact of stress and the possibility of panic. When a "crowd" is tense and insecure and when imagined danger has not been dispelled, the stage is set for the introduction of stimuli to react by panic. The members of the panicked group may act together, but the action probably is illogical, irrational, and dangerous to the group members.[12]

CONCLUSIONS

We are discovering the price we are paying for our democratic way of life and, as men before us discovered, we find that the attitudes, the thought patterns, and intellectual preparation that served us well in the past are not good enough to serve in the future. We should appreciate what our actions and goals are costing us—that if we choose, we may pay for them in pain and illness; but that, through education and mental health, we will decide what actions and goals are faulty and unreal, then alter our direction and pace accordingly.

Democracy is a homely, personal thing. Its strength depends utterly upon the individual, his wisdom and qualities of moral goodness. The psychological, emotional, and spiritual resources of mature, responsible citizens will be of critical importance to the survival of our nation should atomic war reach our homeland. An effective level of common purpose and sound state of mind, achieved through nationwide civil defense and mental health programs, is essential in maintaining the will to victoriously resist the enemy.

RESPONSE OF HUMAN BEINGS ACCIDENTALLY EXPOSED TO SIGNIFICANT FALL-OUT RADIATION

Commander Eugene P. Cronkite (MC), U. S. N., Victor P. Bond, M.D., San Francisco,
Commander Robert A. Conard, Lieut. N. Raphael Shulman, Lieut. Richard S. Farr, (MC), U. S. N.,
Stanton H. Cohn, Ph.D., San Francisco, Charles L. Dunham, M.D., Washington, D. C.
and
Lieut. Col. L. Eugene Browning (MC), U. S. Army

After detonation of a nuclear device in the Marshall Islands during the spring of 1954, radioactive material fell upon several neighboring inhabited atolls.[1] The fall-out material consisted of pulverized and incinerated coral (calcium oxide) coated with radioactive fission products, forced high into the atmosphere by the violence of the explosion. The particulate matter was then distributed over a wide area by the wind structure. The field of radiation resulting from the deposition of this radioactive material on the islands was sufficiently intense to result *in significant whole-body irradiation of the inhabitants.* In addition, the skin was contaminated with the material, and some of it was inhaled and ingested. The calculated whole-body dose of radiation in roentgens as measured in air and the amount of fall-out observed for each of the island groups is shown below. The exposed American servicemen were returned to duty after extensive medical examinations at Kwajalein and at the Tripler General Hospital, Honolulu, T. H. The Utirik people were returned to their native atoll after the initial period of observation. The Rongelap and Ailinginae residents were moved to Majuro Atoll for temporary occupation of dwellings built for them. These gamma ray doses were calculated from field instrument readings taken at the time of evacuation and decay schemes appropriate for the estimated times of exposure. For the sake of brevity, details will be presented only on the more severely exposed Rongelap group and the other groups will be referred to only for comparative purposes.

Calculated Whole Body Dose of Radiation

Island Group	Population	Whole-Body Dose in r	Fall-Out Observed
Rongelap	64 Marshallese	175	Heavy (snow-like)
Ailinginae	18 Marshallese	69	Moderate (mist-like)
Rongerik	28 American servicemen	78	Moderate (mist-like)
Utirik	157 Marshallese	14	None

The detonation of the device was observed in the early morning, and hours later the exposed individuals noticed a snow-like material falling from the sky; this continued for several hours. The material was visible on the ground and sifted into the lightly constructed thatched-roof houses. The material whitened the hair and clung to the skin. During the night following the explosion and for the next two days, about two-thirds of the population developed nausea and 10% vomited and had diarrhea. During this period also, many developed itching and burning of the skin and some reported burning of the eyes with lacrimation. Supervised decontamination and medical care was not possible until the exposed individuals were evacuated to the nearby naval base at Kwajalein. *By this time, initial symptoms had completely* subsided.

An emergency medical team, composed largely of naval personnel from the Naval Medical Research Institute and the U. S. Naval Radiological Defense Laboratory, was organized and sent to the area, arriving on the ninth day after exposure. Complete initial histories and physical examinations and frequent follow-up examinations and treatment for medical conditions were carried out on all personnel. In addition, hematological studies to assay the degree of radiation damage and urinary excretion studies for radioactive materials were performed. It was apparent from initial blood studies that significant radiation had been received, and by 12 to 14 days further evidence of radiation injury was apparent in the form of skin lesions and epilation. With the exception of the development of skin lesions and epilation, physical examinations at no time revealed findings in any group that could be attributed with certainty to radiation.

CLINICAL OBSERVATIONS, THERAPY, AND HEMATOLOGICAL FINDINGS

Since the degree of depression of peripheral blood elements is believed to be the best index of severity of radiation injury, systematic serial determinations were carried out. These determinations consisted of total leukocyte, neutrophil, lymphocyte, and platelet counts and hematocrit determinations. Control groups, as comparable as possible to the exposure groups in respect to age, race, sex, and background, were selected. Findings are expressed in terms of percentage of control values. Significant age and sex difference in blood cell counts were noted in the control groups, and the data are presented in accordance with the differences noted.

The absolute neutrophil count (fig. 1) of both younger and older age groups fell to a value of approximately 70 to 80% of that of the controls during the second week, followed by a period of fluctuation until the fifth week. At this time the beginning of a second depression was noted for both age groups, and a low value of approximately 50% of that of the controls was reached. The

From the Naval Medical Research Institute, Bethesda, Md., and U. S. Naval Radiological Defense Laboratory, San Francisco. Commander Cronkite is now at Brookhaven National Laboratory, Upton, N. Y. Lieut. Farr is now at the University of Chicago, School of Biological and Medical Sciences.

Read before the Section on Military Medicine at the 104th Annual Meeting of the American Medical Association, Atlantic City, June 8, 1955.

Drs. David A. Wood, University of California Hospital, San Francisco, and Edward L. Alpen, U. S. Naval Radiological Defense Laboratory, San Francisco, made the histopathological evaluation of the skin lesions.

The discussion of this paper was opened by Dr. Lee E. Farr, Upton, N. Y., and Major Carl Hanson, Washington, D. C.

[1] Effects of High-Yield Nuclear Explosions, statement by Lewis L. Strauss, chairman, and report by United States Atomic Energy Commission, Atomic Energy Commission, Feb., 1955.

level was maintained at approximately 75% of the control values from the 7th week to the end of the critical period of observation (10th week). The values for the lower age group were below those of the older age group throughout most of the period of observation. The absolute lymphocyte count (fig. 1) of the older age group had fallen by the third day to a value of approximately 55% of the control value. This value was maintained throughout the study, with no definite evidence of an upward trend. The values for the younger age group also fell before the third day to a value of approximately 25% of the control value, after which there was a significant upward trend, recovery being more rapid in the younger age group. Since the mean lymphocyte counts remained essentially constant throughout the study, the fluctuation in total white blood cell count was a reflection of changes in the neutrophil component (fig. 1).

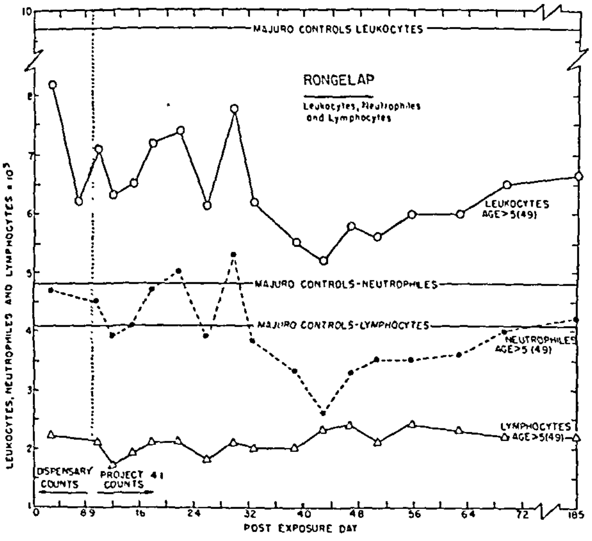

Fig. 1.—Mean leukocyte changes in highest exposure group (64 people).

The sequelae of depression of hemopoiesis are generally considered as the major source of morbidity and mortality from whole-body radiation injury.[2] Therefore, in view of the low leukocyte counts that developed in the Rongelap people, the use of prophylactic administration of antibiotics was given careful consideration. Twenty-seven individuals had absolute neutrophil counts of 2,500 per cubic millimeter or less at some time during the period of observation. Temporary depressions as low as 700-1,000 were observed. Prophylactic admininistration of antibiotics was not instituted because all individuals were under continuous medical observation and it was felt that such drugs might obscure medical indication of treatment and lead to the development of drug-resistant organisms. An epidemic of upper respiratory infection developed between the 27th and 47th days after exposure in all of the exposed groups. Fifty-eight per cent of the Rongelap people were involved. The disease did not appear to be more severe in this than in the other less exposed groups. There was no correlation between leukopenia and incidence of infection.

Platelets were first counted 10 days after exposure (fig. 2), at which time the level in the females were approximately 60% of the appropriate control group. After this, the platelet count fell, reaching a low of approximately 30% of the control value during the fourth week. (At this time counts in 20% of the Rongelap people were below 90,000 platelets per cubic millimeter.) The platelet level rose during the fifth and sixth week and had reached the value noted for the initial counts on the 10th day. A second decrease in platelets developed during the seventh and eighth week, and values remained at approximately 70% of the control values during the remainder of the observation period. The pattern of the platelet counts in the male groups was similar to that noted for the females. Counts of the lower age group, males, were consistently higher than those of the adult group in absolute counts but consistently lower as percentage of control.

There was no evidence of hemorrhage into tissues, even though in 11 individuals platelet count levels reached between 35,000 and 65,000 per cubic millimeter. Two women menstruated when their platelet counts were 150,000 and 130,000 per cubic millimeter respectively. Both experienced excessive menstrual bleeding, insufficient to cause them concern, which subsided without therapy.

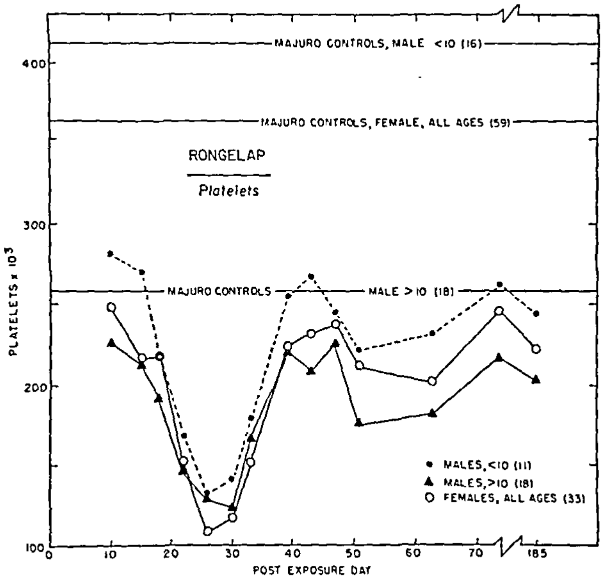

Fig. 2.—Mean platelet changes in highest exposure group (64 people).

Six months after the accident, blood cell counts showed only slight increase over previous ones during the last week (10th) of the initial observation period and were still below control levels. Follow-up studies at one year after the accident showed that the neutrophil counts of the exposed individuals were back to the control level; however, the lymphocytes, monocytes, eosinophils, and platelets were still below control levels, though they were higher than after six months. Hematocrit determinations first done on the 22nd day were slightly below those of the control population. A significant trend in values after this time could not be detected statistically. The less-exposed island groups showed similar, but in most cases less pronounced, hematological change that was consistent with the lower doses calculated for these groups.

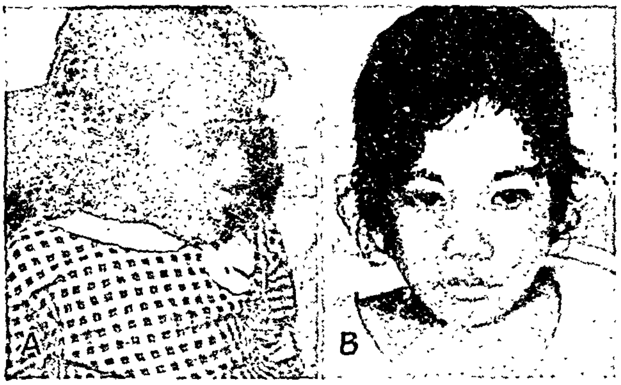

Fig. 3.—*A*, epilation in 7-year-old girl at 28 days. *B*, six months later, showing complete regrowth of hair.

The time course of hematological changes corresponded most closely with the low-dose Japanese groups exposed to radiation from the Hiroshima and Nagasaki bombs[3] in which definite signs of severe radiation exposure were present in some individuals but in which no mortality occurred. Comparison with hematological data in Japanese groups in which fatalities occurred make it probable that exposure in the highest exposure group of Marshallese was moderately severe, probably within 50 to 100 r of the level where some fatalities would have resulted. The skin and internal radioactive contamination were considered not to have contributed significantly to the depression of the hematological elements.

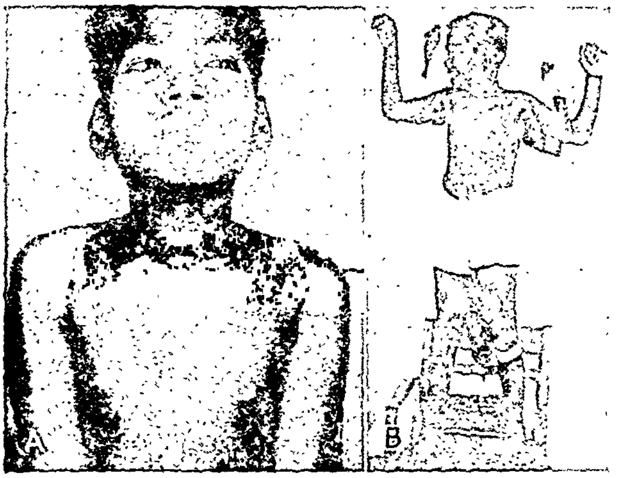

Fig. 4.—*A*, pigmented lesions of neck and antecubital fossae in 13-year-old boy (29 days after exposure). Desquamation with depigmentation of neck lesions has begun. *B*, extensive lesions in 13-year-old boy at 45 days after exposure.

The body weight of individuals in the Rongelap and Ailinginae groups was followed routinely. Adults as well as children lost some weight during the period of observation in spite of the fact that they lived inactive lives and ate heartily. Whether the failure to gain weight was connected with radiation or change in environment is open to question. Four women in the Rongelap group were pregnant when brought to Kwajalein. None of these women had abnormal symptoms referable to radiation. All of the pregnancies have since terminated in delivery of apparently normal babies.

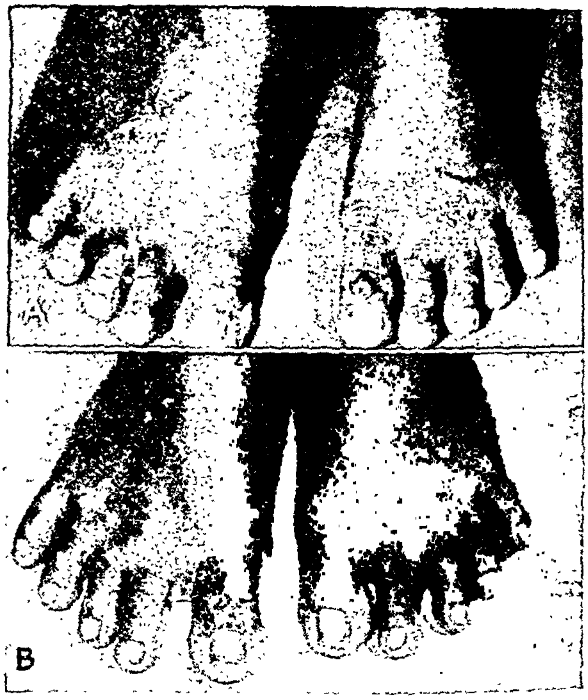

Fig. 5.—*A*, hyperpigmented raised plaques and bullae on dorsum of feet and toes at 28 days. One lesion on left foot shows deeper involvement. Feet were painful at this time. *B*, six months later. Foot lesions have healed with repigmentation, except for depigmented spots persisting in areas where deepest lesions were.

SKIN LESIONS AND EPILATION

Irradiation of the skin resulted largely from beta radiation from the fall-out material deposited on the skin. Due to the complex composition of the radioactive materials, and because of other uncertainties, it was impossible to calculate the skin dose accurately. The dose was sufficiently large, however, to produce epilation and widespread lesions of the skin in 90% of the Rongelap group, beginning about 12 to 14 days after the exposure. In the less heavily exposed groups (Ailinginae and Rongerik), the lesions did not appear until approximately 20 days after the accident. In the Utirik group, radiation lesions of the skin did not appear. The lesions occurred primarily on the exposed parts of the body not protected by clothing. Those who remained under shelter during the fall-out developed less severe or no lesions. Some protection was afforded those who bathed during this period. Almost simultaneously with develop-

Zirkle, ed. 1, New York, McGraw-Hill Book Company, Inc., 1951.

ment of skin lesions, spotty epilation of the scalp was noted (fig. 3*A*). Epilation was usually accompanied or preceded by lesions of the scalp. This was more extensive and severe among the children (birth to 15 years). Over 90% of the children showed some degree of epilation, as compared to 28% in the older age group. Regrowth of hair of normal color and distribution was noted beginning about nine weeks after irradiation and was complete six months after the accident (fig. 3*B*).

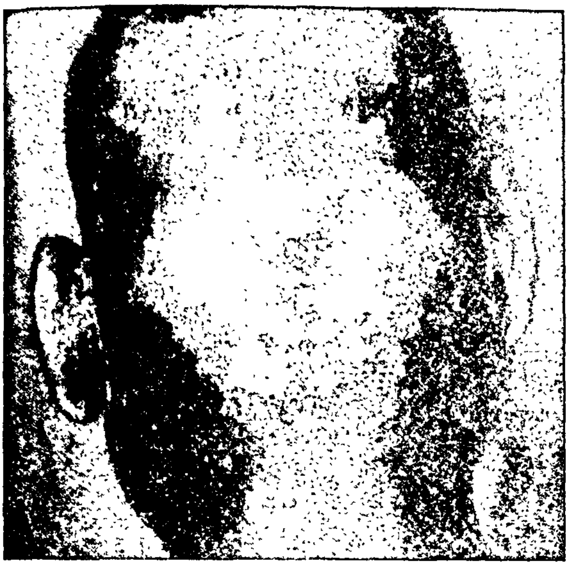

Fig. 6.—Desquamation of back of scalp at 28 days. Epilation occurred earlier in desquamated area. Note persistent ulceration of left ear.

The developing lesions did not follow the identical course as observed by Knowlton and co-workers[4] in individuals after handling concentrated fission products or after other beta burns.[5] Primary and secondary erythema was not observed. The lesions showed differences in latent periods before appearance on different parts of the body and appeared in roughly the following sequential order: scalp, neck, axillary region, antecubital fossae, feet, arms, legs, and trunk. The neck and scalp lesions were most common; however, a substantial number of antecubital fossae lesions and foot lesions were seen. Lesions on the flexor surfaces tended to appear before lesions on extensor surfaces. These differences in latent periods did not appear to be related entirely to the dose to the skin, since severe foot lesions, presumably caused by the foot receiving a larger dose of radiation, did not appear until after other less severe lesions.

The first indication of a lesion was an increase in pigmentation in the form of macules, papules, and raised plaques (fig. 4*A*). Usually these dark pigmented lesions had a dry, thickened, leathery feel. Most lesions were superficial. After several days, dry, scaly desquamation developed from the center of the lesion outward. Desquamation left depigmented areas similar in texture to the surrounding skin (fig. 4*B*). During the next few weeks, the lesions gradually became repigmented and the skin became relatively normal in appearance. Approximately 20% of the group developed deeper lesions. These were seen on the neck, scalp, and ear, and most frequently on the feet (fig. 5 and 6). These lesions were painful and were characterized by wet desquamation with weeping and crusting, and, in some foot lesions, desquamation was preceded by bullous formation (fig. 5*A*). Some lesions became secondarily infected; however, all lesions except one ear lesion healed rapidly and reepithelized in a week or 10 days. The ear lesion took about four months to heal. Repigmentation gradually took place in most lesions, and some of the healing lesions, particularly on the neck, showed development of hyperpigmentation of a grayish, dusky color and a thickening of the skin with "orange-peel" appearance.

Biopsy specimens taken from lesions during the third to fourth week revealed histopathological changes consistent with radiation damage (fig. 7). Spotty transepidermal damage with atrophy and flattening of the rete pegs was a common finding, with areas of relatively normal skin between, emphasizing the particulate nature of the radioactive material. Cells of the malpighian layer showed pleomorphic nuclei, pyknosis, and cytoplasmic halos. Focal disorganization of the malpighian and basal layers was present in extensively damaged areas. In the dermis, telangiectatic vessels were noted where the overlying epidermis showed greatest damage. There was mild edema of the pars papillaris with lymphocytic infiltration, particularly around the telangiectatic vessels. Atrophy of hair follicles was observed.

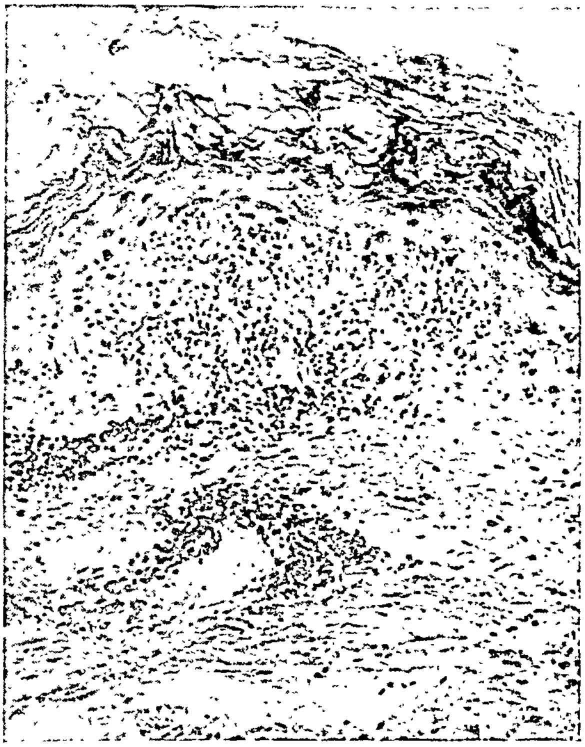

Fig. 7.—Photomicrograph of pigmented skin lesion three weeks after exposure (× 100). Extensive transepidermal damage with less involved areas on either side. Loose lamination of stratum corneum, absence of stratum granulosum, and disorganization of malpighian layer. Dermis shows mild edema of pars reticularis, indistinct capillary loops, moderately pronounced perivascular cellular infiltrate, and mild telangiectasia.

Follow-up studies at six months and one year showed that the hyperpigmentation had in most cases disappeared. At the site of deeper foot lesions and the ear lesions, there were pink-to-white areas that had not repigmented (fig. 5*B*). In these areas the skin appeared slightly atrophic. Treatment of the skin lesions consisted of daily cleansing and symptomatic therapy with the exception of locally applied antibiotic ointments for infected lesions and in one case parenterally given penicillin.

The possibility that cancer might develop at the site of some of these lesions must be considered. Favoring such development are the long life expectancy of the numerous children in the exposed group, constant exposure to tropical sunlight, and the possible influence of additional sublethal whole-body exposure. Against such development are the superficial nature of the lesions, rapid healing with little in the way of residual gross defects, and only minimal evidence of histological damage by six months.

Pigmentation of the semilunar area of the fingernails and toenails was observed about the 23rd day in most of the Marshallese in the higher exposure groups and in the five American Negroes but in none of the white Americans. The pigmentation was beneath the nail and progressed distally with growth of the nail. A similar phenomenon has been observed in a Negro woman after local therapeutic irradiation.[6]

INTERNAL RADIATION HAZARD

Radiochemical analysis of numerous urine samples of exposed personnel showed that the degree of internal absorption of radioactive materials was roughly proportional to the calculated external dose and, therefore, to the concentrations of air-borne fission products. The degree of internal radiation hazard was too low to have contributed significantly to the acute radiation syndrome observed. The concentration and type of internal radioactive contaminants minimize the probability of any significant long-term effects from the internal radiation.

SUMMARY AND CONCLUSIONS

After detonation of a thermonuclear device in the Marshall Islands in the spring of 1954, radioactive fall-out occurred over an area of thousands of square miles beyond the range of thermal and blast injury. Marshallese and Americans were accidentally exposed on islands in this area, receiving whole-body gamma radiation, beta radiation injury to skin, and minimal internal contamination. The highest dose (an estimated 175 r) was received by a group of 64 Marshallese. The dose of radiation received proved to be sublethal. Though there was significant depression of hemopoiesis, no clinical signs or symptoms developed that could be attributed with certainty to this effect. Prophylactic administration of antibiotics or other specific therapy was not found to be indicated.

Skin lesions and epilation developed in 90% of the group beginning about two weeks after the exposure. The lesions occurred largely on exposed parts of the body not protected by clothing, and varying degrees of protection were also afforded those who remained indoors or bathed during the fall-out period. Most of the skin lesions were superficial and exhibited pigmentation; dry, scaly desquamation; and rapid healing with little pain. Some lesions were deeper, exhibiting wet desquamation, and a few became secondarily infected. Treatment was largely palliative except for use of antibiotics for secondarily infected lesions. Histopathological examination of lesions showed changes consistent with radiation damage. Bluish-brown pigmentation was noted in the fingernails and toenails of the dark-skinned people but not in the white Americans. Minimal amounts of radioactive material were detected in the urine. The internal deposition was insufficient to contribute significantly to the acute reaction, and it is believed there is no long-term hazard. Examinations conducted one year after the exposure revealed these people to be in generally good health. Slight depression of lymphocytes and platelets persisted. A few pigment aberrations and minimal atrophy remained at the site of the deeper skin lesions.

RADIOIODINE TREATMENT OF EUTHYROID CARDIAC DISEASE

FOUR YEARS OF EXPERIENCE WITH TWO HUNDRED THIRTY-ONE PATIENTS

Henry L. Jaffe, M.D., Maurice H. Rosenfeld, M.D., Frederick W. Pobirs, M.D.
and
Laurence J. Stuppy, M.D., Los Angeles

Two hundred thirty-one euthyroid, seriously ill cardiac patients have been treated with radioactive iodine (I^{131}) since February, 1950, in the department of radiation therapy and the cardiac outpatient department of the Cedars of Lebanon Hospital in Los Angeles. Of particular interest is the analysis of the original 100 patients treated four years ago.

Radioiodine treatment for euthyroid cardiac invalids was pioneered by Blumgart and his associates in March, 1947. They reported, in August, 1952, their results in the treatment of 39 patients followed for 40 months.[1] In April, 1951, Wolferth and his group [2] gave account f 28 patients treated with radioiodine for intractable angina pectoris. Stuppy,[3] Jaffe,[4] Pobirs,[5] and Rosenfeld [6] reported upon 95 treated patients in November, 1951, and upon end-results in 100 patients in June, 1952.[7] In 1952, Chapman [8] described 23 treated cases. Serber and his group [9] reported 24 cases in February, 1953. Blumgart [10] gave the chairman's address of the Section on Internal Medicine at the annual convention of the American Medical Association, June, 1954, de-

scribing the results in treatment of 1,070 patients from 47 clinics, 64% of whom were observed for longer than one year. Published reports by these authors have been favorable in respect to the treatment of angina pectoris, and, with the exception of Serber,[9] the reports have also been favorable in respect to the treatment of severe congestive failure. Although Wolferth [2] reported upon only 28 patients treated for angina pectoris, he commented in his paper that he and his associates were convinced that radioiodine had a place in the treatment of severe intractable congestive heart failure.

SELECTION OF PATIENTS

Blumgart and his associates [1] have stressed the importance of selecting only patients in whom the disease has been relatively stationary for months or years. They cite as especially unfavorable such rapidly progressive diseases as malignant hypertension and syphilitic aortitis. Other contraindications in their opinion are existing hypothyroidism, active rheumatic fever, recent myocardial infarction, bronchiectasis, cirrhosis of the liver, and emotional instability. Wolferth and his associates [2] require the following conditions before they are willing to apply radioiodine to patients with angina pectoris: 1. The anginal syndrome is so severe that the patient is incapacitated from earning a living, or is awakened so frequently at night that adequate rest is impossible. 2. Response to a careful regimen of life and adequate medicinal treatment has been unsatisfactory. 3. The condition has lasted long enough so that spontaneous improvement is unlikely. 4. No signs of hypothyroidism are present and the uptake of I^{131} in a tracer dose is within normal limits. 5. The blood cholesterol level is not abnormally high. 6. The patient has demonstrated his willingness to cooperate by refraining from using tobacco to excess and by adhering to a low-fat diet.

Serber and his group [9] accepted euthyroid patients with severe recurring angina or repeated episodes of congestive failure uncontrolled by the usual medical means. The criteria of these authors are all excellent guides. We feel that to use radioiodine in the moribund patient is inadvisable, because hypothyroidism can be produced only gradually. In commenting upon the cases of Chapman, Paul D. White [11] stated that radioiodine should be used only for severely ill patients in whom angina pectoris has recurred over a long period of time (more than a year), or for those patients with extreme intractable congestive failure. The ability of collateral circulation to develop and angina to improve spontaneously makes the evaluation of radioiodine treatment even more difficult; but, he stated, treatment is symptomatic, and most patients treated have improved.

High cholesterol blood levels may not be proper grounds upon which to exclude patients from radioiodine treatment. It is likely that constitutional hypercholesteremia in certain euthyroid persons may lead to early atherosclerosis and cardiac disease; however, it is not established that hypercholesteremia of the degree obtained in relative hypothyroidism from radioiodine therapy will accelerate this process. Blumgart and associates [1] found no evidence of increased atherosclerosis in autopsies of five patients with rheumatic heart disease who had been hypothyroid from 1 to 11 years. We have had no autopsies of patients who were suitable for providing us with this kind of information.

DESCRIPTION OF PATIENTS AND THEIR MANAGEMENT

Patients in our series were treated for severe angina pectoris or severe congestive heart failure or for a combination of both. A few patients treated suffered from paroxysmal acute pulmonary edema. Several of these patients with serious heart disease also had troublesome cardiac arrhythmias poorly controlled by drug therapy. The etiology of our cases was rheumatic, hypertensive, arteriosclerotic, congenital, and pulmonary. All of the patients had advanced heart disease and had not responded to the usual modes of therapy. Patients who had active rheumatic fever, or recent coronary occlusions, or who were already hypothyroid were not accepted. Patients with cardiac disease and hyperthyroidism who were treated with radioiodine were not included in this series for analysis.

The first group of 100 patients has been under observation for four years. The second group of 131 patients has been observed from six months to three years, with at least half this group followed for one year. The average follow-up time for all 231 patients was 29 months. Of the 231 patients, 51 were followed medically in the cardiac outpatient department. The other 180 were private patients who were followed by their own physicians. The same plan of management was used for clinic and private patients.

The rationale of treatment is to produce a state of beneficial relative hypothyroidism by lowering the total metabolism of the body, so that the heart has less work to do. Therapy is only symptomatic, and the condition of the heart is in no way changed or cured by radioiodine. In conjunction with radioiodine therapy all other modes of cardiac treatment are given as indicated. After radioiodine treatment, our practice has been to avoid severe symptomatic hypothyroidism, prescribing where necessary thyroid extract in doses of 1/10 to ½ grain (6 to 30 mg.) daily. The clinical courses of the patients have been most carefully followed to detect the earliest symp-

toms of hypothyroidism and to relieve these as much as possible, even before laboratory tests have been definitely positive.

The cooperation of the patient is essential. With the symptoms of his weakened heart masked by the lowered metabolic rate, he might be tempted to expend energy foolishly. We describe for each patient the complete plan of treatment so he knows that this therapy is merely an attempt to lower the metabolic rate of the body and thereby lessen the strain on the heart. He is instructed to recognize the signs of myxedema, such as coldness of the extremities; swelling of the eyelids, face, and tongue; thickened speech; muscle aches; joint pains; bloating; and extreme fatigue. As soon as he realizes any such symptoms in himself, he reports them to his internist, who may then prescribe the proper thyroid medication to control these undesirable symptoms.

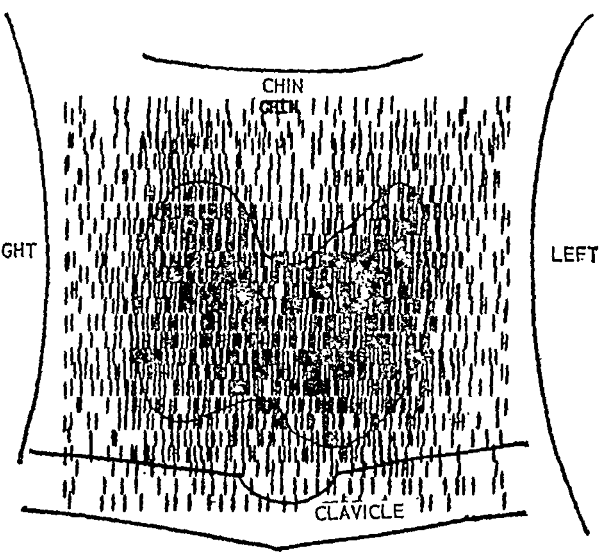

Fig. 1.—"Thyrogram" (diagram of the thyroid gland made by a scintillation counter) made 24 hours after administration of a tracer dose of radioactive iodine (I^{131}).

TECHNIQUE OF RADIOIODINE THERAPY

A tracer dose of 5 μc of I^{131} is given orally to the patient in the department of radiation therapy, and the radioiodine thyroid gland 24-hour uptake is measured. A second dose of radioiodine of 500 μc is given orally after the uptake study has been completed, and a "thyrogram" (silhouette of the thyroid gland made by a scintillation counter[12]) is made the next day (fig. 1). This provides a diagram of the approximate size, shape, and degree of the uptake of the entire thyroid gland. Radioiodine, averaging 6 mc. per dose, is given orally each week until the patient has a total of 30 mc. This is called the first course of treatment. Previous to the thyrogram technique, we had to rely on clinical and uptake studies and other laboratory data for the determination of the effect of the first course of radioiodine. This necessitated waiting two to three months before the post-treatment thyroid uptake test could be done, since there was too much residual radiation activity of the gland *to allow doing an uptake study* before the end of the two-month interval. Now it is possible to check the gland size and function one month after the first course of treatment (fig. 2). If the patient has not improved and the thyrogram indicates that the thyroid gland is still functioning normally (fig. 3) a second course of five weekly oral doses of 6 mc. of I^{131} is prescribed. A third thyrogram is made and the patient's progress evaluated one month after the second course. If necessary, a third course of I^{131} is prescribed, unless the patient already has signs of hypothyroidism.

The size of the dose of radioiodine used varies from clinic to clinic. We prefer to give 6 mc. oral doses of I^{131} at weekly intervals until the patient has received a total of 30 mc. Other clinics have given as much as 100 mc. in a single dose. We have chosen the small dose technique to avoid the danger of suddenly releasing large amounts of thyroxin from the destroyed gland into the blood stream. This might produce a temporary increase in metabolism that in a patient with severe cardiac disease could be detrimental, or even fatal. Another undesirable side-effect of larger doses of I^{131} is radiation thyroiditis, with an increased metabolic rate. In our first 100 patients with this plan of dosage the incidence of thyroiditis was low, and we found little evidence of temporary thyrotoxicosis subsequent to I^{131} therapy. Bone marrow depression is another possible hazard of massive therapeutic doses of I^{131}, but smaller doses have not endangered the patient in this way.

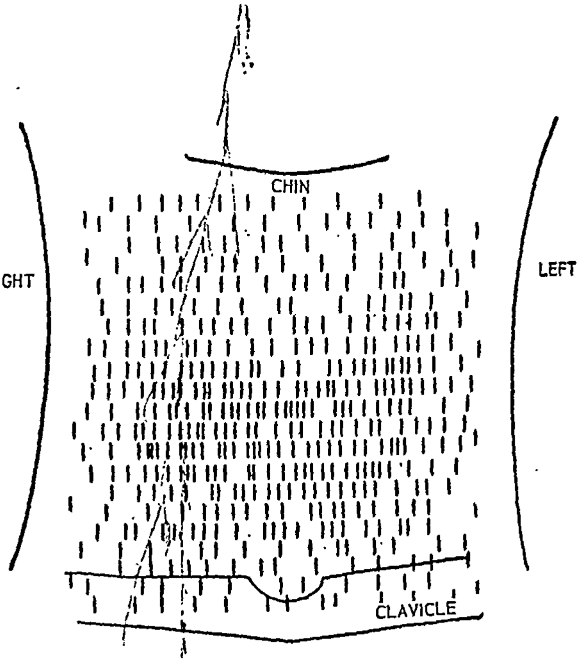

Fig. 2.—Thyrogram made two months after completion of the first course of radioactive iodine treatment. A total of 30 mc. in divided doses was given between Oct. 23 and Nov. 27, 1953. Almost complete reduction in size and function of both lobes is noted.

Safeguards against radiation are necessary when any radioactive material is used therapeutically. Single doses as large as 20 to 100 mc. make the patient a focus of considerable beta and gamma ray activity, and safe treatment usually means hospitalization of these patients so that trained personnel can handle the disposal of excreta. Smaller doses do not produce this problem, since I^{131} has a half-life of eight days, and therefore most persons may be treated as outpatients.

---

[12] Allen, H. C., Jr.; Libby, R. L., and Cassen, B.: The Scintillation in Clinical *Studies of Human* Thyroid Physiology Using I^{131}, [illegible] **11**: 492-511 (May) 1951.

Apparently the radiobiological time factor in euthyroid cardiac patients treated with I^{131} is independent of the size of the single dose or total dose.[13] Symptomatic relief occurred in a comparable interval after a single dose of 25 mc. or five weekly doses of 6 mc. The same percentages of excellent and good results were obtained with multiple small doses of I^{131} as with the single or multiple large doses totaling 100 mc. reported by other authors. Therefore, we have continued treating selected euthyroid incapacitated cardiac patients with a multiple small dose technique. Radioiodine should be used only in a laboratory completely equipped for handling radioisotopes where measurement instruments for calibration of the dosage are provided.

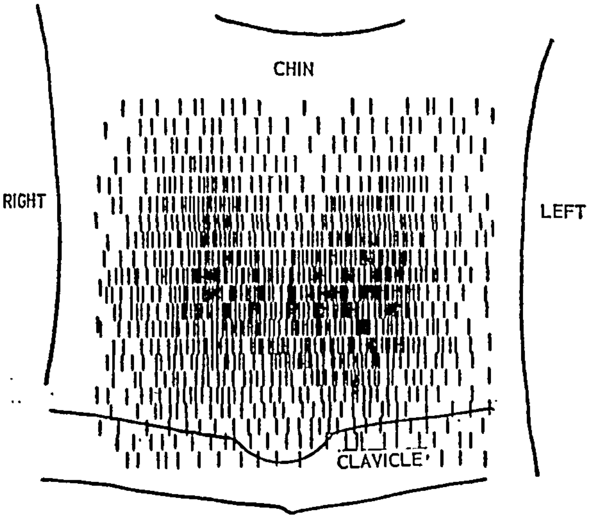

Fig. 3.—Thyrogram showing regeneration of thyroid tissue in both lobes to about 60% of the original size of the thyroid gland indicating gland has ability to recover its function after an apparently total medical thyroidectomy one month previous. A second course of radioactive iodine therapy was prescribed.

USE OF THYROID EXTRACT AND DEGREE OF HYPOTHYROIDISM DESIRABLE

It is our opinion, and the consensus of the opinion of most authors as recorded in the literature, that no greater degree of hypothyroidism should be permitted than adequate clinical relief of cardiac symptoms requires. Wolferth[2] and Serber[9] have used conservative radioiodine dosage. Serber has controlled myxedema where it developed in his patients with 15 to 30 mg. of thyroid extract with no interference with the beneficial effects of radioiodine therapy. Chapman[8] states that patients should not be allowed to develop myxedema but their basal metabolic rate should be kept at –20 to –25%, plasma bound iodine level at 2 to 3 mcg. per 100 cc., and radioiodine uptake at 10 to 20% in 48 hours.

Blumgart and associates,[1] however, according to their early reports have practiced permitting pronounced hypothyroidism, and in some instances complete myxedema, to develop in order to be sure that all thyroid tissue has been affected before administering 6 to 12 mg. of thyroid extract daily. They have adjusted the thyroid extract dosage to maintain the lowest metabolic level associated with the maximum relief of cardiac disease and the minimum discomfort from myxedema. They found in some of their patients that treating with sufficient thyroid extract to obviate symptoms of myxedema resulted in very little cardiac improvement over the pretreatment status. They then stated that in most of their patients they administered 6 to 30 mg. of thyroid extract to maintain basal metabolic rate levels of –20 to –25%. When our patients have shown symptoms of hypothyroidism we have prescribed doses of 12.5 to 30 mg. of thyroid extract daily. We insist that our patients not be allowed to develop the disagreeable clinical picture of severe hypothyroidism or myxedema. Some patients eventually regenerate thyroid tissue and need more radioiodine treatment. This is confirmed by follow-up I^{131} uptake studies and thyrograms that are made at three-month intervals.

RESULTS OF TREATMENT

Evaluation of Results.—The many and diverse clinical problems presented by patients with severe cardiac disease affect the evaluation of beneficial results obtained from radioiodine treatment. Complete symptomatic relief is not the prerequisite for an excellent or worthwhile result. A patient with angina pectoris decubitus who is relieved of the agonizing need to take glyceryl trinitrate (nitroglycerin) repeatedly throughout the day and night receives real help, even though after treatment walking without pain is still impossible. A patient who may be comfortable at rest but who cannot work because of repeated attacks of angina pectoris is greatly benefited if he is improved sufficiently to return to work. A patient with congestive failure and ascites gains much advantage if radioiodine treatment relieves the necessity of repeated paracenteses, so that sodium restriction or the use of mercurial diuretics is sufficient.

TABLE 1.—*Comparison and Summary of Results of Radioiodine Treatment of 231 Euthyroid Cardiac Patients in Two Series*

	1st Series, 100 Patients		2nd Series, 131 Patients		Series Combined, 231 Patients	
Results *	No.	%	No.	%	No.	%
Excellent	55	55	67	51	122	53
Died	23	42	5	7	28	23

Total	100	100	131	100	231	100
Died	45	45	21	16	66	29

* Classified according to Blumgart.[1]

Knowing what relief has been obtained from other forms of medical treatment, and with the clinical problems of each patient crystallized and recorded, we can more accurately evaluate the effect of radioiodine treatment. The improvement in comfort, ability to care for self or to work, reduction in required drugs, and decrease in dangerous attacks of acute pulmonary edema must be weighed against the disadvantages of relative hypothyroidism.

---

[13] Andrews, G. A., and others: Pathologic Changes in Normal Human Thyroid Tissue Following Large Doses of I^{131}, Am. J. Med. 16: 372-381 (March) 1954.

Statistics.—The results of treatment in the total 231 cases treated to date have followed closely the pattern set when the first 100 cases were reported in 1952.[7] Of 231 cases, results were considered excellent in 53%, good in 33%, and there was no improvement in 14%. Comparison of results obtained in the first 100 cases with results in the second group of 131 cases is shown in table 1. The classification used to evaluate and compare results in both groups as presented here is that of Blumgart [1] in which excellent (marked improvement) is defined as markedly improved over pretreatment status, with either no recurrence of symptoms or a marked decrease in the frequency and severity of angina pectoris or congestive failure, despite activity greater than that possible before treatment and good or worthwhile result as definite decrease in frequency and severity of attacks on same activity as before treatment, or able to do considerably more with no increase in angina pectoris or congestive failure.

TABLE 3.—*Radioiodine Treatment of Euthyroid Severely Ill Cardiac Patients, Comparison of Results in the Literature*

Results	Angina Pectoris, %					Congestive Heart Failure, %			
	Jaffe [4]	*Blumgart* [1]	*Serber* [9]	*Wolferth* [2]	*Chapman* [8]	*Jaffe* [4]	*Blumgart* [1]	*Serber* [9]	*Chapman* [8]
Excellent	56	34	31	67	..	53	31	..	..
Good	37	38	23	22	..	28	15	18	..
Total improved	93	72	54	89	45	81	46	18	57
No improvement	6	27	46	11	55	19	54	82	43
Total cases	94	26	13	18	9	78	13	11	7

Excellent results were obtained in 55% of the first 100 cases and 51% of the second group of 131 cases. Results in 28% of the first group were judged good, whereas a greater number of additional good results, 37%, was obtained in the second group. Only 12% of the patients in the second group had no improvement, whereas 17% of the first group had been failures. Better selection of cases and more experience in the management of the treated patients may account for the improved results.

Patients with angina pectoris obtained a greater percentage of benefit than patients with congestive failure or angina and failure combined (table 2). The smaller percentage of patients with angina with no improvement confirms this. In both series, the proportion of excellent results was very nearly the same in patients with angina, congestive failure, and angina plus congestive failure. The patients with angina and congestive failure combined showed the lowest percentage of excellent results and the highest mortality. This might be expected, as those patients with manifestations of both types of cardiac dysfunction would be on the average the most seriously ill.

Of the first 100 patients treated and followed for four years, 45% have already died. The first patient of this group was treated 52 months ago, and the last patient was added to the group 36 months ago, giving a mortality of 45% over a period of 36 to 52 months. Among those 55 patients in the first group of 100 patients who had excellent results, 23 persons (42%) have died. Of those 28 patients who had good results, 7 persons (25%) have died, and of those 17 patients with poor results, 15 persons (88%) have died. Obviously, evaluation of the results obtained referred only to a certain circumscribed period of time. Although a high percentage of patients who had excellent results have died, a definite period of clinical improvement followed radioactive iodine treatment. The results could be considered good for the duration of the patients' lives. No evidence has been observed that radioiodine treatment has shortened the duration of life of these patients or influenced the development of atherosclerosis.

Although the work of the several groups investigating radioiodine as a treatment for euthyroid cardiac disease has been conducted independently, evaluations of the results obtained have been similar (table 3).

SUMMARY

Of 231 patients with euthyroid cardiac disease treated with radioiodine (I^{131}), 100 were followed as long as 52 months but not less than 36 months and 131 were followed as long as 36 months but not less than 6 months. Patients were treated for severe angina pectoris, congestive failure, or a combination of both, resulting from most of the common etiologies for heart disease. The "thyrogram" (a diagram of the thyroid gland made by a scintillation counter) was used to check gland size and function, and the time interval between courses of radioiodine could therefore be shortened. Patients with angina pectoris (94 in number) showed 56% excellent and 37% good results. Only 7% showed no improvement. Patients with congestive failure (78 in all) showed 53% excellent and 28% good results; 19% showed no improvement. A group of 59 patients with angina pectoris and congestive heart failure combined showed 48% excellent and 32% good results; 20% showed no improvement.

4833 Fountain Ave. (29) (Dr. Jaffe).

CLINICAL NOTES

EDEMA AND CONGESTIVE FAILURE RELATED TO ADMINISTRATION OF RAUWOLFIA SERPENTINA

George A. Perera, M.D., New York

Following the administration of alkaloids of Rauwolfia serpentina, the occasional occurrence of temporary sodium retention has been reported.[1] In the course of further experience with these drugs in the treatment of hypertension, fluid retention has now been encountered in five instances, even to the point of extensive edema, pulmonary congestion, and venous pressure elevation. The four women and one man who developed fluid retention all had documented hypertensive vascular disease with no previous history of dyspnea, edema, or cardiac pain. Four had negative urinalyses and one a 1+ proteinuria immediately prior to the episode. Three had been given 0.25 mg. of reserpine (Serpasil) twice daily by mouth, and two had been given Rauwolfia serpentina (Raudixin), 100 mg. twice daily by mouth, all five being on an ambulatory outpatient basis and on a self-selected diet but without extra salt.

In all instances moderate pitting edema of the ankles appeared within a week of the start of therapy. Two subjects went on to develop marked edema of the lower extremities and basal pulmonary rales, and one of these complained of moderate exertional dyspnea and exhibited some periorbital swelling. Both the patients with the more severe degrees of fluid retention, observed after three weeks of continued medication, had gained more than 4 lb. (1.8 kg.) in weight, with the venous pressure in an antecubital vein recorded as 116 and 130 mm. of saline respectively; both had a 1+ proteinuria; and a white blood cell count and differential smear was within normal limits in one. In only one patient of the group of five was there any significant reduction in blood pressure or pulse rate in association with drug administration. None complained of cardiac pain, and none exhibited any irregularities of cardiac rhythm.

No improvement was noted until therapy with the drug was discontinued, each patient having received from three to four weeks of sustained treatment without change in diet or dosage. Within one subsequent week all manifestations of abnormal fluid retention had vanished, one patient spontaneously remarking of her increased urine output. The weight of the two subjects with more marked edema returned to pretreatment levels by the end of the week, and in one of these it was possible to check the venous pressure, which had fallen to 80 mm. of saline. During a period of observation of from one to three months after treatment, no patient developed any recurrent edema or cardiac symptoms. At a later date, one of the patients who had developed marked edema while receiving reserpine was given the same drug in the same dosage for one week; definite pitting edema of the ankles was again apparent, and once more it vanished when administration of reserpine was discontinued.

COMMENT

The association of fluid retention in five patients treated with crude or purified alkaloids of Rauwolfia serpentina seems more than happenstance and, although no balance studies were undertaken, may possibly be related to the occasional sodium retention previously reported. It is difficult to attribute the accumulation of edema to changes in diet. Against the possibility of a coincidental cardiac decompensation in these hypertensive subjects are the negative previous histories, the temporal relationship to drug administration, the rapid remission following cessation of therapy, and the subsequent course. The minimal urinary findings do not suggest a nephrotic episode.

The observation that alkaloids of Rauwolfia serpentina may ocasionally produce fluid retention needs further confirmation, and the mechanism remains to be elucidated. In the meantime, this possibility should be kept in mind, particularly in patients who already have a lowered cardiac reserve.

SUMMARY

In five patients with hypertensive vascular disease, fluid retention occurred after the administration of crude or pure alkaloids of Rauwolfia serpentina. In two of these patients, the fluid retention was severe enough to cause congestive failure.

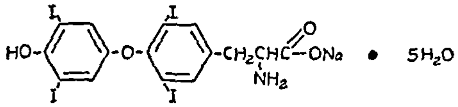
Sodium Levothyroxine.—$C_{15}H_{10}I_4NNaO_4.5H_2O$. — M.W. 889.00. — 3,3′,5,5′-tetraiodothyronine pentahydrate.—The structural formula of sodium levothyroxine may be represented as follows:



Actions and Uses.—Sodium levothyroxine is the sodium salt of the levo isomer of thyroxine (DL-thyroxine). Levothyroxine exhibits approximately twice the activity of the racemic (DL-) form. Sodium levothyroxine, which is more soluble and reportedly more active than the base, levothyroxine, also is more efficiently absorbed by the gastrointestinal tract and is effective in smaller oral doses than mixtures of D-thyroxine and L-thyroxine (thyroxin, U. S. P. XIII; thyroxin fraction, N. N. R. 1947). Approximately 50% of the oral dose of sodium levothyroxine is absorbed. The mean half-time of levothyroxine turnover is reported to be 6.5 days as measured by disappearance of radio-iodine (I^{131}) labeled levothyroxine from the serum in euthyroid subjects. Daily oral administration is cumulative and is capable of producing typical manifestations of hyperthyroidism.

Sodium levothyroxine is useful in the replacement therapy of diminished or absent thyroid function (cretinism, myxedema, and milder forms of hypothyroidism) resulting from primary atrophy, partial or complete absence of the gland (congenitally or surgically acquired), or from the effects of excessive radiation or antithyroid drugs. It should not be employed in hypometabolic states of nonthyroid origin or in conditions not definitely associated with thyroid deficiency. Replacement therapy reverses the symptoms of athyreosis and hypothyroid states and must be maintained to control the disease.

As with other thyroid preparations, overdosage may produce hyperthyroidism, so that it is necessary to keep patients under close observation for the development of signs or symptoms of thyrotoxicosis. Although the chemical purity of sodium levothyroxine permits more uniform standardization than with desiccated thyroid (thyroid, U. S. P.), clinical activity must be determined in each individual case. For purposes of rough comparison, 0.1 mg. of sodium levothyroxine produces the equivalent ical effect of 30 to 60 mg. of thyroid, U. S. P.

Dosage.—Sodium levothyroxine is administered orally. The initial dosage for adults should range from 0.05 to 0.1 mg. daily. The response of the patient should serve as a basis for increments of 0.05 to 0.1 mg. in the daily dosage, and these increases should be made every 1 to 3 weeks until proper metabolic balance is obtained. The daily dosage required to achieve this may vary from 0.02 to 1 mg., but in most patients a maintenance dosage of 0.15 to 0.4 mg. daily is usually adequate. Adjustments in dosage should be gradual to avoid rapid changes. For children the initial dosage should not exceed 0.05 mg. daily. Increments in the daily amount of 0.025 to 0.05 mg. may be made every 1 to 3 weeks until the desired response is obtained.

The effects of overdosage may begin after 4 to 5 days, but they may not become apparent for 1 to 3 weeks. When signs of overdosage appear, medication should be stopped for 2 to 6 days and then resumed at a lower level.

Travenol Laboratories, Inc., cooperated by furnishing scientific data to aid in the evaluation of sodium levothyroxine.

Protoveratrine A and B Maleates.—The maleate salt of a mixture of two alkaloids, isolated by appropriate means, from Veratrum album. The chemical structure of the two alkaloids has not been established.

Actions and Uses.—Protoveratrine A and B maleates have the same actions and uses as the parent esters, protoveratrines A and B. (See New and Nonofficial Remedies 1955, under the monograph on protoveratrines A and B.) The same precautions should be observed in the use of the maleate as with the parent form of the mixture.

Dosage.—Protoveratrine A and B maleates are administered orally. On the basis of comparative molecular weights, approximately 13% more of the maleate salts than of the parent esters is required to provide equivalent dosage; however, the difference is not of particular significance except when therapy may be alternated in patients for whom optimal maintenance dosage has been individualized. Careful adjustment of the dosage for each patient is essential.

The average oral total daily dosage ranges from 1 to 2.5 mg., divided into three to five doses, preferably given after meals and at bedtime, at intervals of 4 to 6 hours. The initial oral dose is 0.5 mg. three times daily (after meals). Increases in dosage are made in accordance with blood pressure measurements at the time of peak action of the drug (1½ to 3 hours after the dose). It is recommended that the morning and evening doses be increased by increments of 0.125 mg. until the desired therapeutic effect or evidence of overdosage is observed. The noon dose is maintained at the 0.5 mg. level. A dosage schedule including between meal and bedtime doses may be more effective in some patients. With the appearance of nausea or vomiting, the preceding dose should be decreased by 0.125 mg.

Eli Lilly & Company cooperated by furnishing scientific data to aid in the evaluation of protoveratrine A and B maleates.

APPROVED EXAMINING BOARDS IN MEDICAL SPECIALTIES

ADVISORY BOARD FOR MEDICAL SPECIALTIES

B. R. Kirklin, Secretary-Treasurer
Rochester, Minn.

Because of the overwhelming amount of material, the following pages concerning the American specialty boards are continued in this issue from the annual Internship and Residency Number of The Journal, *Sept. 24.*—Ed.

The Advisory Board for Medical Specialties was organized in 1933-1934 to coordinate graduate medical education and certification of medical specialists in the United States and Canada. A few specialty boards had been functioning actively and successfully for a number of years prior to the organization of the Advisory Board for Medical Specialties. Their purposes were, primarily, to establish minimum standards of graduate education and training requirements for physicians representing themselves to the public as being specialists, with certification by the boards of candidates after they had been able successfully to pass the boards' examinations. Secondarily, these boards hoped to improve the general standards of graduate medical education and facilities for special training.

It was soon recognized that some formal and official plan of organization must be established. It was clearly essential that an examining board must have the official sanction of the national societies in its given specialty as well as that of its section of the American Medical Association, but there was, at that time, nothing to prevent unofficial groups from organizing examining boards and using the title American board. In order to avoid duplication of effort as well as to coordinate the work of the several boards and other interested groups into a concise and homogeneous plan for betterment, it was deemed advisable to create an advisory board to give consideration to those problems common to all and to represent all organizations concerned.

The Advisory Board is composed of two representatives from each of the approved examining boards in the medical specialties and such other national organizations as are interested in the education, examination, and certification of medical specialists. These representatives are duly elected to this body.

The number of organizations comprising the Advisory Board for Medical Specialties remains the same; namely, 18 specialty boards and 4 other organizations interested in graduate medical education. The total voting membership is still 44. The organizations and their representatives are as follows:

CURRENT MEMBERSHIP IN THE ADVISORY BOARD FOR MEDICAL SPECIALTIES—1955-1956

The Association of American Medical Colleges
John B. Youmans
Stanley E. Dorst *

The American Hospital Association
Albert W. Snoke
Robin C. Buerki *

The Federation of State Medical Boards of the U. S. A.
Creighton Barker
Walter L. Bierring *

The National Board of Medical Examiners
Robert A. Moore
John P. Hubbard †

The American Board of Ophthalmology
Conrad Berens
Merrill J. King *

The American Board of Otolaryngology
Frederick T. Hill
Dean M. Lierle *

The American Board of Obstetrics and Gynecology
Herbert E. Schmitz
Robert L. Faulkner *

The American Board of Dermatology and Syphilology
George Lewis
Beatrice Kesten *

The American Board of Pediatrics
Lee Forrest Hill
John McK. Mitchell *

The American Board of Psychiatry and Neurology
Frederick P. Moersch
Francis Gerty

The American Board of Radiology
H. Dabney Kerr
B. R. Kirklin *

The American Board of Orthopædic Surgery
Clarence H. Heyman
Harold A. Sofield *

The American Board of Urology
Rubin Flocks
Harry Culver *

The American Board of Internal Medicine
Walter L. Palmer
Henry M. Thomas Jr.

The American Board of Pathology
Shields Warren
William B. Wartman *

The American Board of Surgery
Walter G. Maddock
John B. Flick *

The American Board of Anesthesiology
R. J. Whitacre
Curtiss B. Hickcox *

The American Board of Plastic Surgery
Frederick A. Figi
Frank McDowell

The American Board of Neurological Surgery
Francis C. Grant
Leonard T. Furlow *

The American Board of Physical Medicine and Rehabilitation
Robert L. Bennett
Earl C. Elkins *

The American Board of Preventive Medicine
William P. Shepard
Ernest L. Stebbins *

The American Board of Proctology
Louis A. Buie
Stuart T. Ross *

Officers and Committees—1955

Robert A. Moore, National Board of Medical Examiners, President

Walter L. Palmer, American Board of Internal Medicine, Vice-President

B. R. Kirklin, American Board of Radiology, Secretary-Treasurer

MEMBERS OF THE EXECUTIVE COMMITTEE

Term to expire in 1956: Robert L. Faulkner, American Board of Obstetrics and Gynecology

Term to expire in 1957: Walter G. Maddock, American Board of Surgery

COMMITTEE ON STANDARDS AND EXAMINATIONS

Harold A. Sofield, American Board of Orthopædic Surgery, Chairman

Shields Warren, American Board of Pathology

Francis Gerty, American Board of Psychiatry and Neurology

COMMITTEE ON AUDIT AND FINANCE

William B. Wartman, Chairman, American Board of Pathology
Walter G. Maddock, American Board of Surgery

REPRESENTATIVES ON THE ADVISORY COUNCIL ON MEDICAL EDUCATION

Ernest L. Stebbins, American Board of Preventive Medicine
Frederick A. Figi, American Board of Plastic Surgery

---

* Corresponding member.
† Executive secretary of board.

Examining and certifying boards in 19 specialties have been approved by the Council on Medical Education and Hospitals of the American Medical Association and the Advisory Board for Medical Specialties on the basis of minimal standards governing accreditation of specialty boards as formulated by the Council.

The primary purposes of the boards are (1) to conduct investigations and examinations to determine the competence of voluntary candidates for certificates issued by the respective boards, (2) to grant and issue certificates of qualification to candidates successful in demonstrating their proficiency, (3) to stimulate the development of adequate training facilities, (4) to aid in evaluating residencies and fellowships under consideration by the Council on Medical Education and Hospitals of the American Medical Association, and (5) to advise physicians desiring certification as to the course of study and training to be pursued.

The boards are in no sense educational institutions, and the certificate of a board is not to be considered a degree. It does not confer on any person legal qualifications, privileges, or a license to practice medicine or a specialty. The boards do not purport in any way to interfere with or limit the professional activities of any licensed physician, nor do they desire to interfere with any practitioners of medicine in any of their regular or legitimate duties.

Two boards certify candidates in subspecialties. The American Board of Internal Medicine certifies in allergy, cardiovascular disease, gastroenterology, and pulmonary diseases. The American Board of Pediatrics certifies in allergy. Certification in the primary field is a requirement for certification in the subspecialties. The Board of Thoracic Surgery, which is organized as an affiliate board of the American Board of Surgery, requires certification in surgery as a prerequisite to certification in thoracic surgery.

Certificates in special divisions of their specialty are conferred by six boards. The American Board of Obstetrics and Gynecology will issue certificates in obstetrics or gynecology only. The American Board of Otolaryngology grants a limited certificate in endoscopy. The American Board of Pathology issues certificates in pathological anatomy, clinical pathology, a combination of these two fields, pathological anatomy and clinical microbiology, clinical microbiology and clinical chemistry, clinical bacteriology, neuropathology, and clinical microbiology. The American Board of Preventive Medicine issues certificates in public health, aviation medicine, and occupational medicine. The American Board of Psychiatry and Neurology issues separate certificates in psychiatry and in neurology, or a combined certificate for those qualified in both fields. This board also issues supplementary certificates in psychiatry and in neurology. The American Board of Radiology issues certificates in radiology, roentgenology, therapeutic radiology, diagnostic roentgenology, radiological physics, x-ray and gamma-ray physics, and medical nuclear physics.

Each of the boards has published a booklet containing a list of its officers and a brief statement of its organization, purposes, and the qualifications that determine eligibility for certification. A summary of the current data pertaining to each board and the names of its officers are reproduced in the following pages.

There is included in this section a specific statement from each of the boards regarding allowances of credit for service in the armed forces during the present emergency.

Table 1 contains a list of the approved specialty boards, the year of their activation, the number of certificates issued prior to July 1, 1954, and the total number of candidates certified to June 30, 1955. Figures are also given in these two categories showing the numbers certified in the subspecialties and finally the available figures pertaining to special certification by the boards in obstetrics and gynecology, otolaryngology, pathology, preventive medicine, psychiatry and neurology, and radiology.

On July 1, 1954, there were 56,801 physicians certified by the 19 boards. During the year July 1, 1954, to June 30, 1955, a total of 3,843 certificates were issued. Up to this latter date 60,644 physicians have been certified.

On July 1, 1954, a total of 1,362 certificates in subspecialties had been awarded. An additional 35 were awarded in the ensuing year, bringing the total number of certificates issued in the subspecialties to 1,397 on June 30, 1955. Prior to July 1, 1954, the six boards mentioned had issued 12,017 special certificates. During the year ending June 30, 1955, 858 special certificates were issued, bringing the total number awarded to that date to 12,875.

The number of specialists certified each year during the past 15 years by all boards and the cumulative totals are recorded in table 2. Up to June 30, 1955, a total of 60,644 certificates was issued. This does not represent the number of living specialists, but the total number of certificates issued.

The seventh edition of the "Directory of Medical Specialists," compiled by the Advisory Board for Medical Specialties and published in 1955 by the A. N. Marquis Company, Chicago, contains biographic information on the educational background of each living specialist, including those retired from practice, certified by an American board.

CREDIT FOR MILITARY SERVICE

At the suggestion of the Joint Committee on Medical Education in Time of National Emergency, the Advisory Board for Medical Specialties conducted a survey to determine the amount of credit for service in the armed forces during the present emergency that would be given toward specialty board certification. The inquiry addressed to the boards contained the following questions:

> Will your specialty board give preference to those candidates wishing to be examined before going overseas or entering military service?
>
> How much, if any, credit toward your training and/or experience requirements will your board allow candidates while in military service?

In reply to the first question all boards answered in the affirmative. The specialty boards have not lowered their requirements because of the military emergency, but all boards except one have indicated they will grant some credit for military service. The specialty boards have indicated such allowances as follows:

TABLE 1.—*Approved Examining Boards in Medical Specialties*

Name of Board	Year of Activation	Total Certificates Awarded to July 1, 1954	Total Certificates Awarded to June 30, 1955
American Board of Anesthesiology	1937	1,185	1,324
American Board of Dermatology and Syphilology	1932	1,603	1,672

* Included in totals for American Board of Surgery.
† Independent board established in 1949.

Anesthesiology.—No formal training credit is granted for military service unless the physician is assigned to a service hospital with an approved residency training program. Practice time will, however, be granted for military service if the physician is assigned to the anesthesia service.

Dermatology and Syphilology.—Students in training who have served as physicians in the Army, Navy, or U. S. Public Health Service may submit a supplementary application, obtainable from the executive secretary, for possible credit toward experience. This application is not obligatory, but if submitted it must be done prior to or at the time of filing application for examination. It will not be considered until the preliminary registration has been filed. Since the application must be circulated through a committee whose members may be widely separated, several months are often required for a decision. Full-time dermatological military service may be credited in some part toward training, at the discretion of the board, provided it was under the direct supervision of a recognized specialist and provided a significant portion of approved training was completed before the service concerned. The board strongly urges that the candidate supplement his military service by further approved dermatological training before examination. Medical service in the armed forces not credited as training may be credited in part toward the two years of additional dermatological experience required for certification, the amount of credit depending on the circumstances.

TABLE 2.—*Annual Specialty Board Certification, 1940-1955*

Year (Ended March)	Number of Boards in Existence	Number Certified	Cumulated Totals
1940	14	....	15,853

1955 (June 30)	19	3,843	60,644

---

* One board, the American Board of Proctology, did not certify any candidates during this period.

Internal Medicine.—Active duty as a commissioned officer in the armed forces of the United States from June 1, 1950, to July 1, 1954, may be applied as one year of residency credit or one year of practice credit regardless of assignment. Service beyond one year during this interval may only be applied as practice credit on certification by former chiefs of service that assignments of candidates were in the field of internal medicine on a full-time basis in the care of clinical patients, largely on their own responsibility. Active duty in the armed forces as a commissioned officer after July 1, 1954, may not be applied as residency credit unless the candidate has served officially as a resident in a hospital approved for residency training by the Council on Medical Education in internal medicine or in the medical subspecialties recognized by this board. Active duty in the armed forces as a commissioned officer after July 1, 1954, may be applied as practice credit for one year or more on certification by present or former chiefs of service that assignments were in the field of internal medicine on a full-time basis, in the care of clinical patients largely on one's own responsibility. The requirements governing residency credit and practice credit for active duty in the armed forces from Dec. 8, 1941, to Jan. 1, 1947, will remain the same as those governing credit from June 1, 1950, to July 1, 1954, as outlined above.

Neurological Surgery.—The board makes no specific statement regarding military service. This matter is taken up individually with each applicant.

Obstetrics and Gynecology.—Credit will be given for time spent in an obstetric-gynecologic service in an Army or a Navy hospital under supervision on the same basis as a preceptorship, if these departments are supervised by diplomates of the board or recognized obstetricians-gynecologists. Full residency credit may be obtained if such hospital is approved for residency training. The board will review and give consideration to each individual case. Special request must be made for such credits.

Ophthalmology.—No stated credit. Each case is decided according to the time the candidate has spent assigned to a military hospital in ophthalmology and on other factors.

Orthopedic Surgery.—Up to one year of residency credit is given. Each case is determined on its own merits.

Otolaryngology.—Credit is given, but each case is determined on its own merits.

Pathology.—Allows liberal credit toward training when assigned to department of pathology, but candidates must first have had a minimum of one year residency in an approved civilian department of pathology.

Pediatrics.—One year of credit, regardless of assignment, toward two year practice requirement.

Physical Medicine and Rehabilitation.—Credit is given, but each case is determined on its own merits.

Plastic Surgery.—Credit is given on individual basis, considered on candidate's merits.

Preventive Medicine.—Credit for training and experience in public health or aviation medicine while in military service will be considered on an individual basis, depending on the type of service.

Proctology.—At present no credit is granted for military service.

Psychiatry and Neurology.—For military duty after Jan. 1, 1954, only experience credit will be granted for full-time psychiatric and/or neurological duties. Training credit will be granted for residency assignments in regularly approved training programs.

Radiology.—Maximum of one year's credit if assigned to full-time radiological duties.

Surgery.—If a candidate has served in a government hospital or hospitals fully approved for residency training, such training will be acceptable to the board. Military credit may be extended to those candidates who have served in nonapproved hospitals provided that the candidate has had a satisfactory surgical assignment with adequate and diversified clinical material and provided further that his work in surgery is carried out under the supervision of a surgeon acceptable to the board. Any credit extended in the latter category will be considered preceptorship credit and not residency credit.

Thoracic Surgery.—Credit for military service will be decided on an individual basis.

Urology.—No credit for training but credit for one year of practice requirement if training was complete when entering service.

Medical Officer's Professional Training Record.—The Surgeons General of the armed services have distributed a booklet prepared with the assistance of the Council and the Advisory Board for Medical Specialties that is designed to help prospective candidates for certification to maintain an accurate account of work done in the military service. This record will constitute part of the credentials to be submitted to the board on application for certification. The booklet has been printed by the Office of the Secretary of Defense and is distributed by the offices of the Surgeons General to the personnel of their departments. It is highly important that prospective applicants obtain a copy of the "Medical Officer's Professional Training Record" and that they submit their credentials for evaluation by the respective specialty board.

AMERICAN BOARD OF ANESTHESIOLOGY

Board of Directors

Meyer Saklad, President, Providence, R. I.
Rolland J. Whitacre, Vice-President, East Cleveland, Ohio.
Donald L. Burdick, New York.
Stuart C. Cullen, Iowa City.
Frederick P. Haugen, Portland, Ore.
John S. Lundy, Rochester, Minn.
Milton C. Peterson, Kansas City, Mo.
Harvey C. Slocum, Galveston, Texas.
Scott M. Smith, Salt Lake City.
Edward B. Tuohy, La Canada, Calif.
Curtiss B. Hickcox, Secretary-Treasurer, Hartford, Conn.

Past Directors

Charles F. McCuskey, Los Angeles.
E. A. Rovenstine, New York.
Henry S. Ruth, Haverford, Pa.
H. Boyd Stewart, Tulsa, Okla.
Ralph M. Tovell, Hartford, Conn.
Ralph M. Waters, Orlando, Fla.
John W. Winter, San Antonio, Texas.
Paul M. Wood, New York.
Philip D. Woodbridge, Greenfield, Mass.
T. Drysdale Buchanan, New York.*

CERTIFICATION

1. *Method of Making Application.*—Application for certification may be made after a physician has completed one year of approved training. Application must be made to the secretary on a form prescribed by the board, procured only on written request of the applicant, and must be filed at least six months *prior to the date of examination.*

The secretary cannot make any eligibility rulings. These are made only by the entire board on recommendation of the appropriate committees after reviewing the candidate's formal application.

2. *Requirements*

A. After March 27, 1955, each applicant before he shall become eligible for certification in anesthesiology, must:

1. Have graduated from an approved medical school in the United States or Canada or have successfully completed the examinations of the National Board of Medical Examiners.

---

* Deceased

Applicants must have completed an internship of not less than one year in a hospital approved by the Council on Medical Education and Hospitals of the American Medical Association, or its equivalent. Graduates of class B medical schools are not eligible to take the board examinations.

2. Establish in a manner satisfactory to the board that: (*a*) he is a physician duly licensed by law to practice medicine, (*b*) he is of high ethical and professional standing, and (*c*) he has received adequate special training in anesthesiology.

3. Submit proof to the board that he has limited his practice to anesthesiology as a specialty for five calendar years of which at least two have been in formal clinical training approved by the board and that he intends to continue to limit his practice to anesthesiology.

4. Prove to the satisfaction of the board by such written, survey, oral, and practical examinations as the board may prescribe that he is qualified to practice anesthesiology.

5. Personally prepare such case history abstracts of personally conducted procedures pertaining to anesthesiology as the board may specify.

B. Each applicant shall be classified for the purpose of examination and shall be examined in such a manner and under such rules as the board may prescribe. The board, acting as a committee of the whole, reserves the right to reject an applicant for any reason deemed advisable and without stating the same, and the action of the board shall be final.

3. *Examinations*

A. Written Examination: Eligible applicants may take this examination on completion of two years of clinical training approved by the board. Written examinations are conducted every year in about 16 locations throughout the United States on the third Friday in July. Written examinations are of the multiple choice type covering the following subjects: anatomy, chemistry, physics, pharmacology, pathology, and physiology. A passing grade, as determined by the board, is required.

B. Survey Examination: Started in 1949, this examination is conducted by one or more diplomates of the board who visit the applicant in his own locality to observe him in the practice of anesthesiology. The examiner may interview other persons in the community to determine whether the candidate is of high ethical and professional standing. This examination is conducted upon completion of four years limited to anesthesiology (including two years of approved clinical training), and successful completion of the written examination. The board may require more than one survey examination.

C. Oral Examination: Upon completion of the survey examination and five years' limitation of practice to anesthesiology the candidate's qualifications are reviewed and he may be declared eligible to appear for the oral examination. However, at least six months must elapse between the written and oral examination. Examinations are conducted semiannually, in April and October. Examiners consist of directors of the board, plus diplomates who assist as associate examiners. Oral examinations cover all phases of anesthesiology, including the basic sciences and clinical applications.

D. Practical Examination: At the discretion of the board practical demonstrations may be required of the management of the candidate's clinical practice in his local surroundings. This may include inspection of clinical records, reports of departmental activities, library facilities, available apparatus and demonstrations of application of anesthetic agents, methods and all techniques included in anesthesiology. The candidate will also be appraised as to whether he is of high ethical and moral standing in his community.

Applicants are entitled to three consecutive opportunities at yearly intervals to satisfactorily complete the written examination. This three year period begins on the date an applicant is first declared eligible for the written examination.

Oral examinations are given at six month intervals. An applicant is entitled to one oral examination each year for a three year period. In the event that a candidate fails an oral examination, at least 12 months must elapse before he may reappear for the oral examination. The three year period begins on the date an applicant is first declared eligible for the oral examination.

Failure to take an examination constitutes an opportunity just as much as failure to pass an examination. However, under extenuating circumstances such as illness or military service, a candidate may obtain extension of the three year period by writing to the secretary's office prior to the expiration of the three year period.

A fee of $25 will be charged for each repeat in the written and oral examination. The board may, however, at its discretion deny a candidate the privilege of reexamination.

The board reserves the right to limit the number of candidates to be admitted to any examination.

REAPPLICATIONS

Applicants whose original applications were declared void through failure to take the written or oral examination within the three year period will be required to file a new application under the current rules and regulations, pay a new application fee, and submit to both written and oral examination. Applicants whose original applications were declared void through failure to pass the written or oral examination within the three year period, having taken one or more written or oral examinations, must submit proof of an additional year of approved training before their reapplications will be considered. This reapplication will be considered under the current rules and regulations, and the applicant must pay a new application fee and submit to both written and oral examination.

FEE

The fee shall be $125. At least $50 shall be paid on filing the application, of which sum $35 shall be returned if the candidate is not accepted for examination. The remainder ($75) shall be paid before taking the examination.

The board is a nonprofit organization. The fees for examination and certification have been computed on a basis of cost of maintaining an administrative office and conducting examinations. The board reserves the right to increase the fee when necessary.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY

George M. Lewis, President, New York.
Arthur C. Curtis, Vice-President, Ann Arbor, Mich.
Nelson Paul Anderson, Los Angeles.
J. Lamar Callaway, Durham, N. C.
Marcus R. Caro, Chicago.
John H. Lamb, Oklahoma City.
Clinton W. Lane, St. Louis.
Francis W. Lynch, St. Paul.
Beatrice Maher Kesten, Secretary-Treasurer, 1 Haven Ave., New York 32.

Advisory Members

Anthony C. Cipollaro, New York.
Harold N. Cole, Cleveland.
Charles C. Dennie, Kansas City, Mo.
Henry E. Michelson, Minneapolis.
Paul A. O'Leary, Rochester, Minn.
Donald M. Pillsbury, Philadelphia.
Francis E. Senear, Chicago.
Bedford Shelmire, Dallas, Texas.
Arthur W. Stillians, Chicago.
Fred D. Weidman, Philadelphia.

PURPOSES

The board was formed primarily to establish standards of competence for physicians who seek recognition as specialists in dermatology and syphilology. It sets minimum requirements of education and graduate training and takes a keen interest in the development of facilities to provide this training. To this end, the board appraises institutions and persons wishing to train specialists in the field and lends its approval to those offering adequate programs. It examines and certifies qualified applicants who voluntarily comply with its requirements and supplies lists of those certified to the American Medical Association, the Directory of Medical Specialists, and other appropriate organizations and publications. The board assumes the responsibility of setting the standards to be met, but upon the candidate rests the responsibility of acquiring the knowledge to fulfill these standards.

GENERAL REQUIREMENTS FOR ELIGIBILITY FOR EXAMINATION

1. High ethical and professional standing.

2. Graduation from a medical school approved, at the time of the candidate's graduation, by the Council on Medical Education and Hospitals of the American Medical Association. Graduates of schools not on the approved list may be eligible provided they pass part 1 and part 2 of the examinations of the National Board of Medical Examiners.

3. Satisfactory completion of an internship of not less than one year in a hospital approved by the same Council. During three years of World War II internships of nine months only were the rule and fulfilled this requirement. However, all internships completed on July 1, 1947, or thereafter must be of at least 12 months' duration.

4. A state license to practice medicine issued after examination, or by endorsement of the certificate of the National Board of Medical Examiners.

5. Citizenship in the United States or citizenship by birth in Canada or Cuba.

SPECIAL REQUIREMENTS

The following minimum requirements have been established for admission to examination:

Formal training in dermatology and related subjects of not less than three years. This training may be obtained as a resident, fellow, or graduate student in the institutions recognized by the Council on Medical Education and Hospitals of the American Medical Association and approved by the American Board of Dermatology and Syphilology. One month in each year may be taken as a vacation. Vacations may not be postponed from one year to another. Candidates will be eligible for the written examination when three full years have elapsed since the beginning of training.

The formal training shall include:

At least one year full-time in an institution approved for three year training.

Graduate training in the basic medical sciences. (They are listed in the syllabus.)

Carefully supervised clinical and laboratory work.

Annual examinations or other appraisal in the clinical and laboratory aspects of dermatology and subjects related to it.

METHODS OF TRAINING

The preferred method of training is a three year course in an institution approved for that period. However, apart from the required full-time year in such an institution, the remaining two years may be taken in institutions of lesser approval; or in part or in whole as a preceptorship (q.v.); or in half-time institutional training, the remainder being spent in practice. In the last-mentioned plan, only the institutional work is credited as training. Training must be completed within a span of five years, except where military service or other compelling circumstances shall intervene.

CREDIT FOR MILITARY SERVICE

Students in training who have served as physicians in the Army, Navy, or U. S. Public Health Service may submit a supplementary application, obtainable from the executive secretary, for possible credit towards experience. This application is not obligatory, but if submitted it must be done prior to or at the time of filing application for examination. It will not be considered until the preliminary registration has been filed. Since the application must be circulated through a committee whose members may be widely separated, several months are often required for a decision.

Full-time dermatological military service may be credited in some part toward training, at the discretion of the board, provided it was under the direct supervision of a recognized specialist, and provided a significant portion of approved training was completed before the service concerned.

The board strongly urges that the candidate supplement his military service by further approved dermatological training before examination. Medical service in the armed forces not credited as training may be credited in part toward the two years of additional dermatological experience required for certification, the amount of credit depending on the circumstances.

PRECEPTORSHIP TRAINING

Candidates may take up to two years of their training under the direction of a preceptor approved by the board. Not more than half of each training day may be spent in the office of the preceptor; during the other half day supervised training must be undertaken in an approved institution. The preceptor and the chief of service of the institution are jointly responsible for this training, which must conform to a schedule that the preceptor has filed with the board. Preceptorships may be taken during any two of the years of training. A list of approved preceptors is available.

RESPONSIBILITY

It is the candidate's responsibility to make early contact with the board, to ascertain and observe its regulations, and to file the preliminary registration and the application for certification forms. Candidates should have met the General Requirements (q.v.) before applying for certification. Directors of training are responsible for submitting annual reports on their trainees. Directors should assist the board by having trainees meet the General Requirements.

PRELIMINARY REGISTRATION

Every candidate must file a preliminary registration with the board prior to or at the beginning of training, whether or not plans are complete at the time. This establishes his identity and status as a candidate, and begins his permanent file. It enables the board to detect any deficiencies in meeting the General Requirements or in the contemplated plan of training. The preliminary registration form is obtainable from the office of the board. No fee is involved at this time.

Each candidate should also request a copy of the *Booklet of Information* and the *Syllabus of Graduate Training*.

ESTIMATES OF STATUS

Many candidates write outlining their background to date and asking for an estimate of the further training needed. The board's requirements are published to provide this information. Decisions as to additional training required can be made only by the committee on requirements upon submission of the application for certification form giving details of the training undertaken. A $25 registration fee is to accompany this application. The board acts as a body and through duly constituted committees. Individual members only carry out the rules and regulations of the board.

APPLICATION FOR EXAMINATION

Application for examination may be filed before the end of the formal training period, and must be made before the closing date regularly published in the Examinations and Licensure column of THE JOURNAL of the American Medical Association. Dates of examinations, which may vary, are also published here. Applications should be filed early in order to obtain full advantage of the loan sets of histopathology slides available from the Armed Forces Institute of Pathology. No application will be considered without the accompanying registration fee of $25, which will not be refunded. When all supporting documents have been received the application is submitted to the committee on requirements, which appraises the qualifications of the candidate and decides as to his eligibility for examination. An examination fee of $75 is payable when the candidate is notified that his application is acceptable by the board.

The total fee of $100 has been carefully computed and is used entirely for administrative purposes. Members of the board receive no compensation except for actual expenses connected with the examinations.

EXAMINATIONS

Examinations are designed to ascertain the breadth of the candidate's knowledge in the basic as well as the clinical aspects of dermatology and to test his familiarity with the literature and to gauge his general qualifications as a specialist in this branch of medicine.

All applicants for certification must now pass a comprehensive written examination before they are eligible for the oral test. The written examination is held simultaneously in 20 major cities. Applicants are then required to pass the oral clinical and laboratory examination which is conducted in a clinic. Cases will be seen and discussed with each candidate, and the examiners will seek to ascertain his knowledge of general dermatology as well as of various related subjects.

Candidates whose applications have been accepted may take the next examination after the completion of training. Except in special circumstances, an applicant shall take the examination within a year following the filing of application. A candidate once accepted for an examination will henceforth remain eligible for only two succeeding examinations, unless some compelling circumstance, such as military service, shall intervene.

Candidates who have signified their intention of taking the examination and who fail to appear, or who cancel their request after the final notice has gone out, shall forfeit the examination fee.

The board's records are confidential throughout. Examination marks will not be divulged to anyone. The findings of the board are subject to its discretion and are final. Applications are accepted on this understanding.

REEXAMINATIONS

A candidate who fails or is conditioned will be eligible for a second examination without further formal application, but must give at least 60 days' notice of his wish. As the cost of examination is approximately the same whether in whole or in part, a reexamination fee of $50 will be charged.

If the candidate fails to complete successfully all or part of the examination on two occasions, he must take at least six months' additional full-time training, or a year's half-time training, in an institution approved for three years, before being eligible for further examination. He must then file a new application and pay another examination fee of $75.

A candidate who fails his third examination will be eligible for a fourth examination without formal application. Notice of his intent is to be given 60 days before the examination. A reexamination fee of $50 is required.

If a candidate who has failed or has been conditioned does not appear for reexamination before the expiration of three years, he must make a new application and pay an additional fee of $75 before he can be reexamined.

CERTIFICATES

A certificate granted by this board does not of itself confer any degree or legal qualifications, privileges, or license to practice dermatology or syphilology. The board does not limit or interfere with the professional activity of any duly licensed physician. The granting of its certificate indicates that the holder has had adequate training in dermatology and has voluntarily fulfilled the requirements of the board.

A certificate is issued when the successful candidate has completed at least five years of dermatological training and experience.

Certificates are issued only to physicians who practice in the United States and its possessions, in Canada, or in Cuba.

A diplomate is to confine his practice to dermatology except for such emergency programs as have been approved in principle by the American Medical Association.

The names of diplomates are sent to the Directory of Medical Specialists, and to other appropriate organizations and publications.

Membership in the local and state medical societies as well as the American Medical Association is strongly recommended.

REVOCATION OF CERTIFICATES

The certificates issued by the board are issued subject to the provisions of its certificate of incorporation and of its bylaws, and each certificate is subject to revocation in the event that: (*a*) the issuance of such certificate or its receipt by the physician so certified shall have been contrary to any of the provisions of the certificate of incorporation or bylaws; or (*b*) the physician so certified shall not have been eligible to receive such certificate, irrespective of whether or not the facts constituting him so ineligible were known to or could have been ascertained by the directors of the board at the time of the issuance of such certificates; or (*c*) the physician so certified shall have made any misstatement of fact in his application for such certificate or in any other statement or representation to the board or its representatives; or (*d*) the physician so certified shall have been convicted by a court of competent jurisdiction of a felony or of any misdemeanor involving, in the opinion of the board of directors, moral turpitude in connection with his practice of medicine; or (*e*) the physician so certified shall have had his license to practice medicine revoked or shall have been disciplined or censured as a physician by any court or other body having proper jurisdiction and authority.

CHANGE IN INSTITUTIONAL STATUS

When the term of approval of an institution changes, a candidate is given credit by the board for the training year already in progress, on the prior basis. Further work will be credited according to the new status.

PRECEPTORS

A preceptor is one who takes a candidate into his office for part-time training. A dermatologist who wishes this responsible designation must be: (1) a diplomate of the board of at least five years' standing; (2) a recognized teacher of professorial rank on the dermatological staff of an institution approved for three years of training by the board; and (3) recommended as suitable by the chief of staff of that institution. He must be willing to submit regular reports on the student's training on forms supplied by the board.

ADVERTISING

It is not considered good form for a diplomate to advertise to the lay public the board's recognition of his training and ability. He should not use commercial methods and avenues. It is proper to include a statement or phrase such as "Diplomate of the American Board of Dermatology and Syphilology" in announcement cards when opening an office, or after the author's name in a medical publication when the association with a hospital, medical school, or medical society is also mentioned. If the diplomate is in doubt, it would be well to consult the board before placing his good name in jeopardy.

PUBLICATIONS OF THE BOARD

1. Booklet of Information. Every candidate should request a copy, as he will be held responsible for knowing its contents.
2. Syllabus of Graduate Training. This is designed (*a*) to inform the candidate of the field to be covered in his preparation; (*b*) to aid medical schools and hospitals by outlining the scope of teaching deemed advisable.
3. Booklet of Questions from the written examinations. $1.00.

AMERICAN BOARD OF INTERNAL MEDICINE

Chester M. Jones, Chairman, Boston.

RESPONSIBILITIES OF THE BOARD

The major object of the board is to pass judgment on the competence of internists who desire certification—not to determine who shall or shall not practice internal medicine as a specialty.

The American Board of Internal Medicine is not concerned with any mechanism that gains special privileges or specific recognition for those physicians who have been certified in internal medicine. It has never been the intent of the board to define requirements for membership on the staffs of hospitals.

The board endorses completely the stand of the American Board of Surgery, which "specifically disclaims interest in or recognition of differential emoluments that may be based on certification."

REQUIREMENTS FOR ADMISSION TO EXAMINATION AND CERTIFICATION

Each applicant for certification by this board must satisfy the qualifications listed below: General Qualifications 1 and 2 and Professional Qualifications, paragraphs 1-10. For exceptions to the requirements 3 and 4 under Professional Qualifications see paragraph 7.

GENERAL QUALIFICATIONS

1. All candidates must be citizens of the United or Canada.

2. All candidates must present evidence of satisfactory moral and ethical standing in the medical profession.

PROFESSIONAL QUALIFICATIONS

1. Graduation from a medical school approved by the Council on Medical Education and Hospitals of the American Medical Association at the date of graduation.

2. Satisfactory completion of an approved internship of not less than 12 months.[1]

3. Residency or fellowship approved by the Council on Medical Education and Hospitals of the American Medical Association in internal medicine according to the following plan (Plan A) or one of the alternate plans described under paragraph 4.

Plan A: A residency or fellowship in internal medicine for a period of not less than three years in a hospital or other institution approved by the Council on Medical Education and Hospitals of the American Medical Association for residency or fellowship in internal medicine. In such instance in which a resident's nominal status differs from that of the other hospital residents, he must furnish the board with certification by the chief of the medical service and the medical director of the hospital that he actually performed the full duties of a resident as a bona fide member of the residency program. In addition, two years of adequate clinical experience in the practice of internal medicine following graduate training will be required. The board will accept the following equivalents as satisfying one year only of the three years of residency or fellowship to which this paragraph refers. (Two years must be in the field of general internal medicine.)

(*a*) If 12 months of a two year approved internship in a hospital approved for residency training in internal medicine is limited to the medical service and medical specialties, credit will be granted for a first year of assistant residency. The remaining two years of residency training must be in the general field of internal medicine. Certification by the chief of the medical service as to compliance with this requirement must accompany application.

(*b*) One year of approved residency in one of the medical specialties: allergy, cardiovascular disease, gastroenterology, hematology, pulmonary diseases, neurology, pediatrics, psychiatry, dermatology and syphilology.

(*c*) One year of approved residency in pathology.

(*d*) One year as a graduate student or as an instructor in an approved medical school on a full-time basis in bacteriology, biochemistry, pathology, pharmacology, physiology, or internal medicine.

(*e*) An advanced degree in the medical sciences, provided the work has been done and degree obtained after graduation from medical school.

NOTE.—Graduate training credit for the time involved will be allowed candidates who take and satisfactorily complete postgraduate courses in internal medicine or the basic medical sciences provided by accredited medical schools on a full-time basis. This ruling shall not apply to courses of less than three months' or more than 12 months' duration. A certificate of creditable performance, based in part, at least, on a formal examination on completion of the course, will be required.

NOTE.—Fellowship or research assignments not approved by the Council on Medical Education and Hospitals will require certification by the chief of service that such assignment was equivalent in graduate training opportunities and patient responsibilities to that of an approved residency in internal medicine or the subspecialties recognized by the board. This certification must be presented before application is filed.

4. Alternate Training Plans: The board firmly believes that the plan of intensive training prescribed above offers the best opportunity for a young physician to prepare himself to meet his responsibilities as a specialist in internal medicine. It is recognized, however, that capable persons may accomplish the same result in a longer period of time during which the training is less intensive. The board realizes that a number of medical graduates cannot follow the shorter and more desirable plan either because suitable residencies are not available or, in some instances, because of personal and economic reasons. Accordingly, the board has modified its previous regulations governing eligibility for admission to examination. In doing so the board has not modified its standards of examination. It has liberalized its eligibility requirements for admission to examination by accepting half-time formal training and the practice of internal medicine under favorable circumstances as to professional hospital contacts, in lieu of part of the full-time requirements. It is hoped that by this means exceptional individuals may acquire a knowledge of medicine and experience in its application sufficient to qualify for examination.

The program previously described (Plan A), which consists of three years of formal training in an approved residency or its equivalent, following internship, and followed by two additional years in the practice of internal medicine, is recommended by the board. Variations in this program are now subject to the following regulations.

(*a*) In all instances, one year of approved internship and one year of approved residency will be required, except as indicated under Plan G. The graduate training credit of one year heretofore granted as a result of active duty as a commissioned officer in the armed forces during the period beginning Dec. 7, 1941, and ending Jan. 1, 1947, and during the Korean emergency beginning June 1, 1950, and ending July 1, 1954, may not be applied in satisfaction of the one year of approved residency referred to in Plans D, E, or F unless the candidate's assignment is considered by the board to have been equivalent to an approved residency.

(*b*) Following one year of internship and two years of approved residency,[2] the remaining requirements may be satisfied by:

Plan B; that is, by two years of half-time formal training followed by two years of practice limited to internal medicine, or by

---

[1] During the period in which the 9-9-9 program was in effect an approved internship of 9 months will satisfy the requirement of 12 months. A residency of nine months is considered as nine months only.

[2] For the second year of approved residency one of the equivalents described under 3-Professional Qualifications may be substituted.

Plan C; that is, by five years of practice limited to internal medicine.

(*c*) Following one year internship and one year of approved residency, the remaining requirements may be satisfied by:

Plan D[3]; that is, by four years of half-time formal training followed by two years of practice limited to internal medicine; or by:

Plan E[3]; that is, by two years of half-time formal training followed by five years of practice limited to internal medicine, or by:

Plan F; that is, by eight years of practice limited to internal medicine.

(*d*) Physicians who have practiced internal medicine for 12 years following an approved internship may qualify for the examinations without further training (Plan G).

Half-time formal training under expanded plans B, D, and E is defined as follows:

1. Half-time[3] as an instructor in clinical medicine in a recognized medical school in the United States or Canada.
2. Half-time[3] in a research fellowship sponsored by a recognized medical school in the United States or Canada.
3. Half-time[3] as a graduate student in an approved graduate medical school in the United States or Canada.

5. Practice Requirements: A period of not less than two years (to be completed by the time of the first written examination) of adequate clinical experience in the practice of internal medicine. This requirement may be satisfied by independent practice or in association with a recognized internist following completion of formal training.

6. Graduates of Foreign Medical Schools: All candidates who are graduates of foreign medical schools must meet the following requirements as a minimum:

(*a*) The physician must be a citizen of the United States.

(*b*) The physician must furnish proof in the form and to the extent deemed adequate by the board that he (or she) has graduated from a medical school after completing a four year full-time course in medicine.

(*c*) The physician must have a license to practice in one or more states of the United States, and have been in active practice confined to internal medicine within the state of legal residence for at least two years.

(*d*) Graduates of foreign medical schools prior to 1930 may qualify under the alternate plans of the board the same as graduates of approved medical schools in the United States.

(*e*) Graduates of foreign schools in 1930 and thereafter must, in addition to all other requirements, satisfy the requirements of one year of approved internship, and three years of approved residency or fellowship in the United States, followed by at least two years of practice limited to the field of internal medicine in the United States. If, however, their school of graduation is "recognized" by the Council on Medical Education and Hospitals of the American Medical Association, graduates of foreign schools may qualify under the various plans of the board the same as graduates of approved medical schools in the United States.

7. Candidates Graduating Prior to 1937: Candidates graduating from approved medical schools in the United States or Canada prior to 1937 may qualify for admission to examination provided their practice has been limited to internal medicine for at least two years prior to application and provided they are identified as internists by their colleagues in their community.

8. Preceptor Training: Preceptor-type training is not recognized in satisfaction of any part of the three year requirement of formal graduate training.

9. Credit for Service in the Medical Corps of the Armed Forces of the United States and Canada:

(*a*) Active duty as a commissioned officer in the Medical Corps prior to Jan. 1, 1947, may be applied as one year of residency credit or one year of practice credit, regardless of assignment. Service beyond one year may be applied as practice credit on certification of former chiefs of service that assignment were in the field of internal medicine on a a full-time basis in the care of clinical patients largely on one's own responsibility.

(*b*) Active duty as a commissioned officer in the Medical Corps from Jan. 1, 1947, to June 1, 1950, may only be applied as practice on the certification of former chiefs of service as referred to in paragraph (*a*).

(*c*) Active duty as a commissioned officer in the Medical Corps for the period June 1, 1950, to July 1, 1954, may be applied as one year of residency credit or one year of practice credit regardless of assignment. Service beyond one year may only be applied as practice credit on the certification of former chiefs of service as referred to in paragraph (*a*).

(*d*) Active duty as a commissioned officer in the Medical Corps after July 1, 1954, may only be applied as practice credit on the certification of chiefs of service as referred to in paragraph (*a*).

(*e*) Residency credit automatically granted for active service in the Medical Corps of the armed forces was discontinued as of July 1, 1954.

10. Graduates of the Chicago Medical School prior to approval by the Council on Medical Education and Hospitals of the American Medical Association and graduates of the Middlesex School of Medicine who received their degree in medicine prior to Jan. 1, 1951, and who have fulfilled all of the requirements set forth under Professional Qualifications, (Requirements for Admission to Examination and Certification), and an approved residency or fellowship of three years' duration (Plan A) and two years of practice in internal medicine may apply and, at the discretion of the executive committee or of the board, be admitted to examination.

PRINCIPLES OF TRAINING

The American Board of Internal Medicine is interested in the fact that the candidate has embarked on a career of study voluntarily and has thereby expressed the desire to excel and to participate personally in the world's progress in medicine.

Preparation must be based on years of continuous thoughtful study. Therefore, in suggesting a program for those who wish advice, the board hopes to assist the candidates to avoid inferior and superficial programs that may lead to failure and disappointment in later years.

The board believes that all internists should have a sound fundamental knowledge of anatomy, bacteriology, biochemistry, pathology, pharmacology, and physiology. Such knowledge is essential to the continued progress of any internist. The board anticipates that adequate training will be obtained in the basic sciences as applied to internal medicine during a formal three year residency program.

The board wishes to emphasize that time and training are but a means to the end of acquiring a broad knowledge of internal medicine, which the candidate must demonstrate to the board in order to justify it in certifying that he is competent to practice internal medicine as a specialty. The responsibility of acquiring the knowledge rests with the candidate. The responsibility of maintaining the standards of knowledge required for certification rests with the board.

APPLICATION

Candidates for examination must make their application on a prescribed form, which may be obtained from the office of the executive secretary-treasurer.

The application must contain a record of the candidate's premedical and medical training as well as of internships, residencies, graduate study, hospital or dispensary staff appointments, teaching positions, service in the armed forces, membership in medical societies, medical papers published, and the names of four well-known internists to whom the board may write for professional and character reference.

---

[3] Half-time formal training is regarded as four hours per day for six days per week. It is required that half-time formal training will be verified by the head of the department. Verification must accompany application.

The application must be accompanied by one recent, signed photograph of the candidate mounted on the application, and the registration and examination fee of $40 to cover the written examination, of which $25 will be refunded if the application is disapproved. Upon application for admission to the oral examination, an additional fee of $50 will be required. Upon notification of certification by the board, a further fee of $10 to cover cost of certification will be required.

The requirements of graduate training and two years of practice in the field of internal medicine must be satisfied before a candidate is eligible to apply for admission.

If three or more years elapse before a candidate completes his certification, the board will require the candidate to file a new application.

METHOD OF EXAMINATION—WRITTEN AND ORAL

The examination for certification by the board comprise two parts: part 1 is written; part 2 is clinical and is an oral examination. The written examination is held simultaneously in different sections of the United States, Canada, and outside continental limits of the United States wherever eligible candidates are located. Only one written examination will be given each year. This examination will be held on the third Monday in October. This examination is divided into a morning and afternoon period for each of which three hours are allowed. The questions are of the multiple choice type, framed in such manner as the board elects, and designed to test the candidate's basic clinical acumen and his knowledge of applied physiology, anatomy, physiological chemistry, pathology, bacteriology, and pharmacology as related to internal medicine.

Candidates must pass the written examination before admission to the oral examination will be authorized. Oral examinations are held near the time and place of the annual meetings of the American Medical Association and the American College of Physicians and at such other times and places as are necessary. Announcements of all oral examinations will appear in the *Annals of Internal Medicine* and THE JOURNAL of the American Medical Association. Applications cannot be accepted until the schedule is announced in the publications referred to and cannot be accepted after the closing date as announced.

The oral examination will be conducted under the direct supervision of the board. It will be given by members of the Board of Internal Medicine with the assistance of such guest examiners as may be selected. Oral examinations are conducted at the bedside of each of two patients previously assigned to each candidate. Forty-five minutes will be allowed for the examination of each of the patients before the candidate is examined orally. Candidates will be expected to present in a concise, orderly fashion pertinent facts in the history and diagnosis. Demonstration of important physical findings will be requested by the examiner. During the oral examination questions will be asked concerning diagnostic and therapeutic procedures related to the problems under discussion and to any other aspects of internal medicine. Conciseness and clarity of statement as well as evidence of clinical maturity will be searched for, in addition to factual knowledge. Furthermore, the candidate should be prepared to demonstrate his ability to interpret objective demonstrations of roentgenologic, pathological, hematological, electrocardiographic, and other abnormalities.

REEXAMINATION—WRITTEN AND ORAL

A. *Written Examination*

1. The interval between the first and second written examinations will be not less than one year.
2. The interval between the second and third written examinations will be not less than two years.
3. The interval between all written examinations that may be permitted after failure of a third written examination will be two years. Admission to any subsequent written examination after failure of the third one may be granted at the discretion of the board.
4. A fee of $25 is required for each written reexamination. This fee is due upon application for reexamination.

B. *Oral Examination*

1. The interval between the first and second oral examinations will be not less than one year.
2. The interval between the second and third oral examinations will be not less than two years.
3. A candidate who fails the oral examination for the third time will be required to pass the written examination again before further oral examinations are permitted. Having done this, he becomes subject to the same regulations and priorities in respect to the oral examination as apply to candidates who pass the written examination for the first time.
4. A fee of $50 is required for each oral reexamination. The fee is due upon application for reexamination.
5. The effective date of the changes referred to governing readmission to written and oral examinations will be Jan. 1, 1956.

NOTE.—Candidates are not required to repeat the examinations within the specified time limits. A longer interval may be elected between both written and oral examinations. Candidates who elect an interval of three years or more between examinations must file new applications.

CANCELLATIONS

A candidate who cancels his assignment for a written or an oral examination after cards of admission are mailed will be required to pay a special fee in the amount of $10 before a subsequent examination, unless his cancellation was due to personal illness or that of immediate family. This provision becomes necessary because of the large number of cancellations after complete arrangements have been made, and the expense incident thereto.

CERTIFICATES

The certificate issued by the American Board of Internal Medicine shall be in such form as to comply with the articles of incorporation and the bylaws and shall be signed by the officers and members of the board and shall bear the official seal of the board.

Certificates of the board will be issued to candidates who have satisfactorily completed the written and oral examinations and have been officially certified by the board.

SUBSPECIALTY BOARDS

Allergy, cardiovascular disease, gastroenterology, and pulmonary diseases are recognized subspecialties.

Each subspecialty application is individually considered and acted upon by the subspecialty board concerned. The candidate is not eligible for examination until his application has been approved by the subspecialty board concerned and confirmed by this board. Please see Internship and Residency Number of THE JOURNAL of the American Medical Association for statement of requirements.

All candidates must pass the written and oral examinations in internal medicine before admission to examination in a subspecialty of medicine referred to. The subspecialty examinations are oral only and may be taken at a scheduled subspecialty examination subsequent to the candidate's certification in internal medicine. Announcement of the subspecialty examinations will appear in THE JOURNAL of the American Medical Association and the *Annals of Internal Medicine.*

Upon request to the office of the executive secretary-treasurer application forms will be forwarded and should be returned to his office when completed.

INFORMATION ON CERTIFICATION IN ALLERGY BY THE AMERICAN BOARD OF INTERNAL MEDICINE

1. Two years, full time, including training both in allergy and internal medicine in an approved allergy clinic and hospital; or

2. One year, full time, including training in allergy and internal medicine in an approved allergy clinic and hospital, and two additional years of attendance and participation at least two half days weekly at an approved allergy clinic; or

3. Five years of attendance and participation at least two half days weekly at an approved allergy clinic; or

4. Twelve years in the practice of allergy after fulfilling the professional qualifications for certification in internal medicine, with evidence of sustained scientific interest.

5. All candidates who desire consideration in allergy must be certified in internal medicine before applying for admission to examination in allergy.

The candidate should be prepared for oral and clinical examination in the anatomy, pathology, physiology, and biochemistry of reactions of hypersensitivity. This will include immunology, immunochemistry, atopy, allergy of infection, collagen disease, and experimental hypersensitivity. He should be proficient in clinical diagnosis, laboratory procedures, and in the treatment of allergic diseases. He should be familiar with the physiology of respiration, especially as modified by bronchial asthma and pulmonary emphysema and with the pharmacology of drugs used.

NOTE.—Fellowship or research assignments not approved by the Council on Medical Education and Hospitals will require certification by the chief of service that such assignment was equivalent in graduate training opportunities and patient responsibilities to that of an approved residency in allergy recognized by the board. This certification must be presented before the application is filed.

RECOMMENDATIONS OF THE SUBSPECIALTY BOARD ON CARDIOVASCULAR DISEASE CONCERNING QUALIFICATIONS OF CANDIDATES FOR CERTIFICATION IN THIS SUBSPECIALTY

The applicant should be of good character and excellent standing in his community, as attested by letters from sponsors of known integrity.

The applicant should have reached a state of maturity compatible with the acquisition of sufficient factual knowledge and experience to form a basis for sound judgment. The board believes that only exceptional persons are sufficiently mature for this subspecialty before the age of 35 years or less than 10 years after graduation from medical school.

The board will make exception to this general rule of admission to examination, under unusual circumstances, largely to avoid injustice to the younger men of outstanding ability.

The candidate must have given clear evidence of his deep and constant interest in cardiovascular disease over a period of years. The board is particularly interested in recommending for examination those applicants whose records indicate that their interest in cardiovascular disease will probably be sustained throughout life, and that their knowledge of the subject will constantly grow. Achievements in the field of research are regarded as evidence of such interest, but publication of articles or prolonged training in research work is not considered essential. Consideration will be given to the circumstances of each applicant's training and experience; those who have been in communities and institutions that offered excellent opportunities for contributions to the knowledge of cardiovascular disease will be expected to have made such contributions. Consideration will be given to the difference in experience of those whose opportunities for research have been more limited.

In most cases, *it is deemed essential that the candidate*, after thorough training in internal medicine, shall have received at least one full year of postgraduate education in cardiovascular disease, preferably under the guidance of a person known to be experienced and sound. Qualifications will be appraised by the cardiovascular board and admission of the applicant to the examination will be determined by a majority opinion of the board.

Every candidate admitted to the certifying examination in cardiovascular disease will be expected to possess specialized knowledge of the kind indicated below. This list is by no means complete; it is intended to indicate the nature, rather than the extent, of the knowledge every applicant should have. In terms of its scope it should be regarded as the minimum, not the maximum. Persons possessing special knowledge and training in peripheral vascular disease may be expected to have a higher standard required in the examination in that portion of the field than in the certain details of other branches of cardiology, and the converse may be similarly applied.

1. Full and accurate knowledge of the anatomy of the normal and diseased heart, including its relationships to the external chest and to the other mediastinal structures. A comprehensive anatomic knowledge of all important blood vessels including their aberrant locations.

2. A thorough knowledge of the normal and pathological physiology of the heart and peripheral circulation.

3. Detailed knowledge of the diagnostic signs that permit the recognition of all important diseases of the heart and blood vessels, such as arteriosclerosis, arteriosclerotic heart disease, syphilitic heart disease, rheumatic heart disease, constrictive pericarditis, auricular and ventricular septal defects, coronary thrombosis with myocardial infarction, thromboangitis obliterans, Raynaud's syndrome, coarctation of the aorta, aneurysm, patent ductus, arteriosus, periarteritis nodosa and lymphedema.

4. Familiarity with the special methods used in the study of diseases of the heart and blood vessels. In the case of the heart, these include such techniques as electrocardiography, roentgenography, catheterization and angiocardiography; in the case of vascular disease, such techniques as the use of the oscillometer and thermocouple, arteriography, and venography, reflex vasodilatation, the cold pressor test, color changes with evaluation, dependency, temperature, etc.

5. Accurate knowledge of the pathological changes associated with the more important diseases of the heart and blood vessels, sufficient to enable the candidate correctly to evaluate the pathological condition from gross specimens or microscopic sections.

6. Fairly extensive and detailed knowledge of the pharmacology relating to heart and blood vessels. This must include full knowledge of the important relationship of the autonomic nervous system both to the heart and to the peripheral vessels, and the effects of stimulation or paralysis of the various parts of the autonomic system by drugs or by surgical methods. The candidate should be intimately familiar with the use and effects of such important drugs as digitalis, quinidine, heparin, papaverine, epinephrine, dicumarol, penicillin, diuretics, sedatives, etc.

7. A sound understanding of the indications for conservative therapy, as well as for surgical procedures, in cardiac and peripheral vascular diseases (patency of the ductus arteriosus, arteriovenous anastomoses, constrictive pericarditis, scalenus, anticus syndrome, etc.).

In summary, it is the desire of the American Board of Internal Medicine and its Subspecialty Board in Cardiovascular Disease that physicians shall not be admitted to the certifying examinations unless they have exceptional qualifications as individuals and as experts in this subspecialty of medicine.

INFORMATION ON CERTIFICATION IN GASTROENTEROLOGY BY THE AMERICAN BOARD OF INTERNAL MEDICINE

A. Professional Standing

The candidate must have at least two letters from recognized internists or gastroenterologists, which must attest to the candidate's professional qualifications and ethical standing, whether he is specializing in gastroenterology and if not entirely, giving an opinion as to approximately how much of his work is devoted to it.

B. Education

1. The candidate must admit proof of adequately supervised training in the recognized gastroenterologic procedures, including gastric and hepatobiliary function tests, proctosigmoidoscopy and gastrointestinal roentgenology (film interpretation).

2. The candidate must present evidence of fulfillment of one of the following requirements:

   (*a*) Formal graduate course in gastroenterology, full time for at least eight months in a recognized institution.

   (*b*) Residency or fellowship for at least one year in gastroenterology under tutelage of a recognized specialist.

   (*c*) In the absence of (*a*) and (*b*), attendance and active participation in a ward service or in a gastrointestinal clinic, recognized in standing, for at least five years.

3. If requirements (*a*) or (*b*) under the above heading have been met, only three years of (*c*) will be required.

C. Practice

At least 60% of the candidate's work must have been devoted to gastroenterology for at least three years before application.

INFORMATION ON CERTIFICATION IN PULMONARY DISEASES BY THE AMERICAN BOARD OF INTERNAL MEDICINE

1. Candidates for certification in pulmonary diseases shall fulfill the requirements of the American Board of Internal Medicine as to:

(*a*) General qualifications.

(*b*) Professional education.

(*c*) Special training.

2. In addition to the general requirements of the American Board of Internal Medicine, candidates shall:

(*a*) Have completed a special training period in pulmonary diseases to include at least a year's work in a sanatorium or hospital for tuberculosis and at least another year in the practice of pulmonary diseases in such an institution or in association with an older man competent in this field.

(*b*) Submit an application to the advisory board in this specialty, which must be approved by all of the members of this board.

(*c*) Pass the written and oral examination of the American Board of Internal Medicine.

(*d*) Pass the oral and practical examination in pulmonary diseases.

AMERICAN BOARD OF NEUROLOGICAL SURGERY

Francis C. Grant, Chairman, Philadelphia.
Howard A. Brown, San Francisco.
George Baker, Rochester, Minn.
Eldridge Campbell, Albany, N. Y.
William V. Cone, Montreal, Canada.
Franc Ingraham, Boston.
Edgar Kahn, Ann Arbor, Mich.
A. Earl Walker, Baltimore.
James C. White, Boston.
Edgar Fincher, Emory University, Ga.
Leonard T. Furlow, Secretary-Treasurer, Washington University Medical School, St. Louis.

GENERAL QUALIFICATIONS

1. Moral and ethical standing in the profession satisfactory to the board of directors.

2. It shall be discretionary with the board to accept for examination candidates who have been in practice more than six years but whose formal training fails to meet the full requirements.

3. Properly qualified candidates who are permanent residents in and citizens of other countries and are legally qualified to practice medicine there, and who have received their training in neurological surgery in the United States of America or Canada may apply for certification by the American Board of Neurological Surgery.

4. A special certificate may be issued to foreign (not United States of America or Canadian citizens) candidates who have received their training in neurological surgery in the United States of America or Canada and who are returning to their own country at the end of their training period, upon passing successfully the regular examinations of this board, without completion of the requirement of two years in the practice of neurological surgery. This special certificate shall be appropriately identified to distinguish it from the regular certificate of this board.

PRELIMINARY PROFESSIONAL STANDING

1. Graduation from a medical school that is acceptable to the American Board of Neurological Surgery.

2. Completion of a surgical internship of not less than one in a hospital acceptable to the board, or its equivalent opinion of the board. (A one year rotating internship ot satisfy this requirement.)

SPECIAL TRAINING

A period of graduate study of not less than four years beyond the year of general surgical training in an approved hospital, or in a recognized graduate school of medicine acceptable to the American Board of Neurological Surgery. Of this training period, at least 30 months must be devoted to clinical neurological surgery. The training in clinical neurological surgery *must be progressive and not obtained* during repeated short periods in a number of institutions. It is preferable that at least two years of this training be had in one institution, and the board will not ordinarily approve periods of training in clinical neurological surgery of less than one year.

Furthermore the candidate must prepare himself to pass a board examination in general surgery, organic neurology, neuropathology, neuroanatomy, neurophysiology, neuro-ophthalmology, and neuroradiology.

An additional period of not less than two years of satisfactory independent practice of neurological surgery.

The above represents only the minimum requirements of eligibility for examination for certification by the board.

APPLICATIONS

An application on the official application blank in such form as may be adopted from time to time by the board of directors, in order to be considered at any meeting, must be in the hands of the secretary-treasurer of the board not less than six months before the date of such meeting.

The secretary-treasurer of the board on receipt of an application shall forthwith make inquiries from those to whom the candidate refers and from such other persons as the secretary-treasurer may deem desirable, after which he shall forward the application to the committee on credentials. This committee shall consider the application and other information available and notify the secretary-treasurer its recommendation whether or not the applicant is acceptable. The certification of a candidate shall be approved by a majority of the members of the entire board at any meeting held for such certification.

PAYMENT OF FEES

The fee for certification, with or without examination, shall be $100.

The candidate for examination on filing his application shall accompany it with an application fee of $25. When notified by the secretary-treasurer that he is eligible for examination he shall send the examination fee of $75 to the secretary-treasurer at least two weeks before the date of the examination.

REEXAMINATION

A candidate who has failed in one examination is eligible for reexamination in the subject, or subjects, in which he failed within three years, on payment of a reexamination fee of $25. A candidate who has failed in one examination and who does not apply for reexamination within three years, or a person who has applied within that time but who has failed a second time, will be considered a new applicant.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY

Walter T. Dannreuther, President, New York.
F. Bayard Carter, Vice-President, Durham, N. C.
Robert A. Kimbrough, Jr., Vice-President, Philadelphia.
Willard R. Cooke, Galveston, Texas.
Daniel G. Morton, Los Angeles.
John L. Parks, Washington, D. C.
Herbert E. Schmitz, Chicago.
Robert L. Faulkner, Secretary-Treasurer, 2105 Adelbert Rd., Cleveland 6.
Lawrence M. Randall, Assistant Secretary, Rochester, Minn.

REQUIREMENTS

Each applicant before he may become eligible to receive such certificate or other evidence of recognition:

1. Must have had conferred on him a degree in medicine by an institution of learning approved by the Advisory Board for Medical Specialties and the Council on Medical Education and Hospitals of the American Medical Association.

2. Must establish in a manner satisfactory to the board of directors that he is a physician duly licensed to practice medicine in the United States or Canada and is a member of his county or district medical society, and

(*a*) that he is of high ethical and professional standing.

(*b*) that he has received at least minimal training bilaterally, i. e., in both obstetrics and gynecology. Training in one branch only is no longer sufficient for qualification. The term "minimal training" as used here is at present defined as meaning at least one year of full-time formal training, in the branch of either obstetrics or gynecology relegated to a minor role in a candidate's training program as related to his preference and plans for practice. The required total of formal residency training is three years.

(*c*) that physicians otherwise qualified, who were graduated before Jan. 1, 1939, and whose required training was in obstetrics or gynecology alone, and who have confined their practice to obstetrics or gynecology for at least five years immediately prior to application, be accepted for examination as candidates for certification in either obstetrics or gynecology. In all other respects requirements for eligibility remain the same as for those physicians graduated since 1939. At least a fundamental knowledge of both obstetrics and gynecology is essential regardless of whether a candidate's practice is limited to one or the other branch.

3. Must make application for investigation of his credentials and a survey of his character.

4. Must assure the board that he is limiting his practice to obstetrics and/or gynecology and that he intends to continue to do so, except for possible military duties. Candidates must have been in practice limited to the specialty for two years, following completion of their specialty training.

This board will not accept applicants for examination who are not full citizens of the United States or of Canada, though they may be residents of either country. Foreign-born applicants must have been certified by either the National Board of Medical Examiners or licensed to practice medicine in the United States or Canada by a state or provincial board of licensure. Notarized statements, not original citizenship papers, must be furnished when the application is filed attesting to the fact of full citizenship in the United States or Canada, if the applicant is foreign born. Further, there will be required a probationary period of at least three years from the date of licensure in the practice of medicine in these countries before such a candidate may be admitted to examination.

Applicants who have been certified by one of the other American specialty examining boards will not be eligible for certification by this board until they have relinquished the certificate previously conferred, except upon special action to the contrary taken by the American Board of Obstetrics and Gynecology.

The board has ruled that physicians who accept male patients in their private or other practice, for operative or other care, cannot be regarded as specialists in obstetrics and gynecology, except by special ruling when this is related to active military duty.

This board deprecates engagement in fields of practice other than that in which candidates profess to be specialists. The board does not exclude from examination, however, obstetricians-gynecologists who practice abdominal surgery and urology in the female because of the correlation of these activities. The sole exception to this provision is that it is permissible for candidates of the American Board of Obstetrics and Gynecology to participate in emergency care plans operated under the auspices of district, county, or state medical societies.

Military service or any other similar patriotic service, such as work with Selective Service boards, etc., have not been construed as nonlimitation of practice in violation of the board regulations. Officers (regular or reserves) certified by this board and on duty with "Family Dependent Services" are expected to be permitted to limit their work to the specialty, as in civilian life, and not be engaged regularly in general or other practice.

The minimal requirements for all candidates will be uniform as follows:

1. Completion of at least one year intern service in a hospital approved by the Council on Medical Education and Hospitals of the American Medical Association. This need not be a general rotating internship, although this latter is preferred.

The board accepts the fifth or "intern" medical school year required at some schools in lieu of the usual fifth or intern "clinical training" year following graduation.

2. A minimum of seven years of training and practice after the first intern year, to include at least three years of residency training in clinical obstetrics-gynecology in approved institutions, or adequate preceptorship training. (See section on Preceptorship Training.) Following completion of acceptable training two years of post-training practice limited to the specialty are required.

The Council on Medical Education and Hospitals of the American Medical Association listed for the first time in 1950 (*J. A. M. A.*, April 15, 1950, pages 1216, 1204-1211), 149 inspected and approved one year residencies in general surgery "as offering training in general surgery . . . in preparation for residencies in surgical specialties." Such residencies are recommended by this board as desirable additional preparation, particularly when they provide opportunities for training in abdominal surgery. (See Internship and Residency issues of THE JOURNAL for lists.) As noted above, such service may be included in the total minimal eight years required after graduation.

Post-training practice period may include full-time medical school or other positions within the specialty, and actual practice within the specialty as an assistant, associate, or independently.

Periods of residency in obstetrics-gynecology in excess of the required three years will not be accepted as a substitute for any part of the two required years of post-training practice except in the cases of men advancing from their residency training into and planning to remain in full-time teaching positions in medical schools and their affiliated hospitals.

3. Basic science training should emphasize the relation of the basic sciences, anatomy, pathology, physiology, biochemistry, and bacteriology to the application of surgical principles which are fundamental in all branches of surgery. More especially, for this specialty there should be training in infertility, endocrinology, oncology, irradiation therapy, electrotherapy, psychosomatic medicine, and other nonoperative methods of diagnosis and treatment. In addition, the candidate must understand and be trained in the care of emergencies, shock, hemorrhage, blood replacement, electrolyte and fluid balance, protein and nitrogen balance, choice of anesthetics, chemotherapy, acidosis and alkalosis, narcotics and hypnotics, wound healing, and so on.

Studies in the basic sciences may be integrated with the clinical work or may be given separately.

SPECIAL CREDITS AND RULINGS

The board conformed with the general acceleration in programs in medical education in that it will accept a period of nine "accelerated" months as an academic year in satisfying the requirement for each of three years of residency training. Such allowances can be made only for services during the wartime period of the official "accelerated program" and are not made for services before 1943 or after the discontinuance of this acceleration in 1946.

No formal graduate courses are required. If taken, credit will not exceed six months. Fellowships will be evaluated individually for credits by the credentials committee.

An applicant serving under military orders in an Army or a Navy hospital in an obstetric-gynecologic service under supervision may be given the same credit as if he were working under a preceptor, if these departments are supervised by diplomates of this board or recognized obstetricians-gynecologists. He may obtain full residency credit if such hospital is officially approved and listed for residency training in this specialty. The credentials committee of the board will review and give consideration to each individual case. Special request must be made for such credits.

A blank log-book entitled "Medical Officers Professional Training Record" is obtainable from the offices of the Surgeons General. This record should be carefully kept and attested while in military service.

APPLICATION AND FEES

Application must be made on a special blank which will be furnished by the secretary's office and must be forwarded with the other required credentials and the application fee to the secretary's office not later than Oct. 1, 1955.

Candidates currently applying for admission to the examinations for certification are required to submit with their application a plain typewritten list of all patients admitted to the hospitals where they practice, for the year preceding their application or the year prior to their request for reopening of their application, with the diagnosis, pathological diagnosis, nature of treatment, and end result.

The application fee is $25 and is not returnable.

The examination fee is $100 and is payable when the candidate is notified of acceptance for examination. This fee is not returnable after the candidate has been officially accepted by the credentials committee and notified to report for examination.

If the candidate fails the part 2 examination on his original application, he may exercise the privilege of one reexamination (See Examinations, Part 2) but he will be required to pay a fee of $25 for such reexamination on making request that his application be reopened for this purpose. This ruling is effective on applications originally made after June 1, 1949.

The fees have been carefully computed on a basis of cost of examinations and are used entirely for administrative expenses. Examiners and associate examiners serve as such without compensation other than actual expenses.

Many prospective candidates write the secretary's office outlining in their letters their training qualifications and asking informally if they are eligible, if this training has been sufficient and, if not, what is still lacking. Any candidate should be able to make a fair estimate of his eligibility after studying these requirements.

Individual officers and directors cannot and will not make any such estimates or rulings. These are made only by the credentials committee after reviewing such requests made on a special form provided for this purpose, and submitted to the secretary for an appraisal with the fee of $15 to cover clerical expenses involved. This form is designated the "Application for Appraisal of Incomplete Training."

Personal interviews cannot be granted by the secretary or other directors of the board unless requested by the board.

Appraisal of Incomplete Training Forms should not be filed if application for certification has already been filed. This is unnecessary duplication.

All candidates must comply with the board regulations in effect for the year in which the examination is taken, regardless of when the original application was filed.

Applicants declared ineligible for admission to examination may request reopening of their applications within two years of the filing date without payment of an additional application fee. When a candidate requests that his application be reopened, he must supply the board with information to justify such further consideration. A request for the reopening of an application declared ineligible by reason of insufficient training, nonlimitation of practice, or similar items may not be approved in less than two years, although application may be made as specified above to avoid payment of an additional fee. This approval time may be reduced under exceptional circumstances. The request must have adequate supporting evidence of additional training and experience to warrant reconsideration. Preceptorship or Supplemental Training Blanks should be used for such reports, and these will be supplied on request.

After two ineligibility or postponement rulings on any candidate's application, an entirely new application must be submitted (with or without fee, according to current requirements) in order to bring data down to date. The essential feature of this should be evidence of additional training and experience.

Applicants declared eligible but who fail to exercise the examination privilege within three years of the date of filing the application are required to file a new and current application and to pay a new application fee.

Candidates should offer as sponsors or references two diplomates of this board with whom they are presently in contact, rather than men under whom they served as residents only. It is required that sponsors be from the candidate's community and currently acquainted with the candidate and his ability in his practice of the specialty.

On notice of acceptance for admission to examination, examination fee is due and also case records, which should be shipped by the candidate to the secretary's office as soon as possible and not later than the date of the part 1 written examination.

The candidate should make immediate acknowledgment of his notice of acceptance, at which time he will notify the secretary's office about when to expect his case reports.

EXAMINATIONS

Part 1 examinations are scheduled annually for early in February. The results cannot usually be mailed from the secretary's office until after April 1 following the examination. Arrangements will be made for candidates to report in any convenient city where there may be a diplomate of this board to conduct or supervise the written examination, which will be sent out from the board's office under sealed cover.

Special arrangement will be made through senior officers for conducting the written portion of the part 1 examination for men in military service. Such candidates are requested to keep the secretary's office informed at all times of changes in their mailing addresses.

All applicants accepted for examination will be required to obtain a passing grade in both the written examination and a review of case reports (part 1), before becoming eligible for the oral-clinical and pathology examinations (part 2). The passing grade for the written examination and case reports is 75%. A candidate whose grade in either or both falls below 75% is conditioned.

Reexamination for the removal of conditions in part 1 may be taken after one year but within three years after the first failure, without payment of an additional fee.

Application for reexamination in part 1 must be made by the candidate prior to Nov. 1 of any year.

Requests for reexamination in the written portion of part 1 and requests for resubmission of case reports must be filed prior to Oct. 1, 1955.

Candidates who successfully complete the part 1 examination proceed automatically to the part 2 examination held later in the year.

Requests for reexamination in part 2 must be made prior to Feb. 1, 1956.

Candidates appearing for reexamination under a new application after two previous failures will not be required, if they have passed all or part of the part 1 examinations on their first application, to repeat such examination items already successfully cleared.

Part 1.—Examination consists of:

1. A comprehensive written examination, conducted annually, including questions on both obstetrics and gynecology and related basic sciences. The written examination will be limited to a maximum period of three hours.

2. The filing, as early as possible, and not later than the date of the written examination, of 20 obstetric and gynecologic case reports, in condensed form. (See sections on Case Reports.)

Results on case reports submitted for review prior to the written examination will be announced simultaneously with those of the latter; candidates who take the written examination but fail to submit case reports on or before the date of the written examination cannot be given the grade on the latter until their case reports have been received and graded.

Part 2.—The oral-clinical and pathology examinations given all candidates are conducted by the entire board and the associate examiners. Advance announcements of examination dates and place will be made in medical journals throughout the country. (Scheduled for Chicago, May 11 to 20, 1956.)

Examination consists of:

1. Oral examination before two or more examiners.

An endeavor is made to adapt the details of the oral examination to each candidate's experience and practice. The examination is particularly directed to ascertain his familiarity with recent obstetric and gynecologic literature, the related basic sciences, the breadth of his clinical experience, and his general qualifications as a specialist in obstetrics and gynecology.

2. Pathology examination.

The candidate is expected to identify and to discuss several obstetric and gynecologic pathological specimens and microscopic sections.

Examiners report orally on each candidate to the assembled board, after which the results of their investigations are considered jointly by the entire board and associate examiners. After a general consideration of the details of the candidate's oral and pathology examinations, including a review of his capability and general adaptability, the candidate is passed or failed by the entire board of directors.

The final action of the board is based on the candidate's ethical and professional record, training and attainments, as well as on the results of his formal examination.

When a candidate fails in part 2 of the examination, he is not required to repeat part 1 but is required to repeat part 2 only. One reexamination may be taken within three years of the original examination and first failure without formal reapplication papers. Requests for reopening of the candidate's original application must be filed with a reexamination fee of $25 (See Application and Fees). Application for reexamination in part 2 must be made by the candidate prior to Feb. 1 of any year. Data regarding additional training or experience and medical school or hospital appointments acquired in the interim must be cited in the letter and verified on a Supplemental Training Form obtained from the office of the secretary of the board.

The reexamination fee will be effective only on original applications filed subsequent to the date of this announcement, namely, June 1, 1949.

The candidate may be allowed to reappear at the examination following the one failed by him. The board may, at its discretion, deny the candidate the privilege of reexamination.

Failure to exercise the privilege of reexamination within three years entails the filing of a new application with the usual application and examination fees.

After two failures in either part 1 or part 2 on the first application, the candidate may reapply with a new application and reapplication fee of $25 and reexamination fee of $100 and be readmitted to examinations once only. Exceptions to this ruling can be made only by action of the entire board of directors in annual session, usually to be based on evidence of additional training and experience sufficient to warrant such action.

CASE REPORTS

Case reports are to be sent by the candidate to the secretary as soon as possible after receiving notification of eligibility, and not later than the date of the part 1 written examination.

In the case of candidates applying for unilateral certification, case reports must pertain to the branch for which application is made.

Twenty important obstetric and gynecologic case reports, in condensed form, are required. Five cases may concern major illnesses, not necessarily operative. These reports must include a variety of material rather than a number of reports of one type. Case reports from one residency's service shall not be more than five in number.

Men holding full-time medical school faculty appointments may submit the remainder of their case records from this full-time, non-private practice, but post-training service. (See Requirements.)

The candidate should prepare and maintain in his possession a carbon copy of his case records in case of possible loss in shipping.

Evidence of adequate follow-up examination pertinent to each individual case must be submitted.

The candidate should submit separate verified index lists, in duplicate, for each individual hospital at which operations were performed. All of these must be formally signed by the responsible hospital official (preferably the hospital superintendent), attesting in each instance that the candidate was the operator.

In the upper left-hand corner of each index sheet there should appear:

Candidate's name; and name and address of hospital.

The data for each patient should be tabulated horizontally, reading thus:

1. Sequence number of case report (1 to 20).
2. Whether patient was from the candidate's residency service or his own private or ward practice, as follows: "Res. Serv." or "Own Practice." All records failing to have this information will not be considered acceptable.
3. Patient's name or identifying initials, age, parity.
4. Date of patient's admission and hospital admission number.
5. Date of patient's operation.
6. Date of patient's discharge.
7. Dates of follow-up examinations.

At the foot of each index sheet should be placed the attested statement of the hospital official, referred to above. This statement should read as follows:

This is to certify that the above listed case reports have been verified by me from the records of this hospital and these patients operated upon in this institution by Dr.————————; that the admission number and dates specified are correct. This is further to certify that the reports given the following sequence numbers (———— to ———— inclusive) were from the residency service of the afore-mentioned physicians and the reports given the following sequence numbers (——— to ——— inclusive) were from his own practice (ward or private) in this hospital and that in all instances he was the chief operator.

....Signature

......................................Official Title

Date..

Each case report should be typewritten on standard size paper, 8½ x 11 in., and those reports then assembled in sequence. Covers should not be used for separate reports, as this increases their bulk unduly. Reports should be bound loosely together in a light outside cover not larger than 10 x 12 in., so that they may be opened and held like a book. The following items should be observed:

I. Each case report should be headed by identifying information corresponding with that of the index lists, including sequence number, designation as a "Residency" or "Own Practice" case, and so on.

II. The report of the case should begin with:
1. Preoperative diagnosis.
2. Postoperative diagnosis (based on findings).

III. The report should be in condensed form, not reported in detail. Follow-up findings of not less than six months are essential. Omissions of follow-up examinations must be explained and justified.

IV. Obstetric reports that do not include essential pelvic measurements and note of methods used, will be considered incomplete. Surgical reports should contain description of the operation and the reason for selection of the procedure.

V. Each report should conclude with a critical analysis. When this is omitted the report will be considered incomplete and will not be acceptable.

GRADUATE TRAINING RESIDENCIES

This board, through the Council on Medical Education and Hospitals of the American Medical Association, has approved institutions providing acceptable residencies in obstetrics and gynecology.

The American Board of Obstetrics and Gynecology has established the following requirements for its approval of a residency in a hospital department or service:

1. It is most desirable that the chief of service of the department be certified by the board, in the interests of the proper teaching of the specialty of obstetrics and gynecology. In lieu of such certification the board will approve of persons of recognized high professional standing in the specialty. At least one additional senior member of the staff should be similarly qualified.

2. Exceptions to the foregoing, in respect to the certified status of chiefs of service and others as outlined above, can be made by assent of the committee on residency training for adequate and justifiable reasons. As examples of the latter, the degree of F.A.C.S. in obstetrics-gynecology may be accepted in

lieu of one of the two required certifications if the general reputation of the person concerned is known to the committee as national or sectional in scope, or a professorial rank without certification might be acceptable.

3. In instances where the services of obstetrics-gynecology are not combined but are separate in any given hospital, the chief of each such service seeking approval and at least one of his subordinates must be certified or otherwise qualified as outlined above.

If obstetrics and gynecology are not combined in one department, approval can be granted only if arrangements are made for some degree of rotation of residents between both services, provided both services are separately approved.

4. If gynecology is classified in the given hospital as a subdivision or subservice of general surgery, approval cannot be granted for residency training in gynecology. Exceptions have been made if the subdivision of gynecology is headed and staffed by a chief and at least one other certified by this board or otherwise qualified as specialists in obstetrics-gynecology, as specified above, thus insuring an acceptable educational program in obstetrics-gynecology.

5. Departments holding official approvals for residency training are cautioned that their totals of residents appointed must be kept to the number specified in the A. M. A.—American board approval notification. Dilution of training facilities by unauthorized appointment of residents in excess of these numbers may be cause for reinspection and changes in approval status of such hospitals and their special services.

6. For further details of requirements and qualifications for approval for residency training, hospital officials should refer to the latest special issues of THE JOURNAL of the American Medical Association as they appear during each year, dealing with these subjects, or should apply to the Council on Medical Education and Hospitals of the American Medical Association for bulletins entitled Essentials of Approved Residencies and Fellowships.

7. Application for residency approval must be made in triplicate on special forms provided for this purpose. These forms may be obtained from the secretary of the Council on Medical Education and Hospitals of the American Medical Association. All statements amplifying an application should also be made in triplicate. The hospital should keep a duplicate of all papers.

8. The formal application, with all papers, for residency training approval should be submitted primarily to the Council on Medical Education and Hospitals of the American Medical Association, 535 N. Dearborn St., Chicago 10. Action is taken jointly by the Council and this board after survey by the Council.

9. Approvals are granted according to adequacy of the training program and teaching facilities of various institutions on the following several bases: (*a*) one-year approval in obstetrics and gynecology (combined) or one-year approval in obstetrics and/or in gynecology (separate), correlated basic science instruction being an essential part of the first year; (*b*) two-year approval in obstetrics and gynecology (combined) or two-year approval in obstetrics and/or in gynecology (separate), provided there is opportunity in the latter instances for some degree of rotation between the two services as well as laboratory instruction in basic sciences; (*c*) three-year approval in obstetrics and gynecology (combined) or in obstetrics or in gynecology, provided there is opportunity for one to one and one-half years' service in the branch of the specialty opposite to that in which the candidate holds appointment, as well as laboratory instruction in the basic sciences of both branches.

Exchange residencies within the specialty between approved institutions are acceptable and to be encouraged. Many authorities believe that training in more than one institution is broadening to the candidate. "Farming out" to unapproved institutions or services is not acceptable unless the work of such services is directly and carefully supervised by the chiefs of the service in the approved hospital under which the man is actively appointed nd working. This should be attested by such chiefs.

Exchange residencies into other specialties cannot be permitted to subtract from the minimal required three years of training divided between obstetrics-gynecology.

As noted elsewhere, two years of post-training practice limited to the specialty is necessary before a candidate becomes eligible for certification.

This board has no objection to residency services being arranged by hospitals for periods longer than three years, unless this dilutes the candidate's clinical training opportunities too much during the first three years. However, the board does not accept a fourth year, or more, of residency training as a substitute for any part of the required two years of post-training practice. The importance of post-training practice in the specialty is emphasized as an opportunity for maturing of the candidate and for colleague appraisal of a man's ability when working on his own responsibility in his chosen community.

Exception to this ruling may be made for men advancing from their training into and planning to remain in full-time teaching positions. These men then must complete at least two years in such positions. Consequently the only institutions in which men may work as fourth and fifth-year residents and obtain credit for this time as "post-training practice" are those directly affiliated with approved schools of medicine as teaching hospitals for undergraduate instruction. These "full-time" men must hold faculty appointments, must have teaching duties with undergraduate students, must be given independent authority more than that of residents, and must make a declaration of intention to remain in full-time teaching work.

10. Any physician formally obligating himself to serve a residency in a Council on Medical Education and Hospitals of the American Medical Association-American Board of Obstetrics and Gynecology approved hospital and thereby eliminating other possible candidates from the position, who breaks his contract without justifiable cause, either before beginning his service or during his period of service, except by mutual consent and agreement between the candidate and the hospital, may be barred from the examinations for certification at the discretion of the board.

11. It should be recalled by all concerned that credits for graduate training may be obtainable in certain instances for residency or assistantship service in hospitals not officially approved for residency training. Each such case must be individually considered, and credits will be largely dependent on the teaching qualifications of those in charge of the service, and the clinical facilities of the hospital in question.

PRECEPTORSHIP TRAINING

After July 1, 1955, the board will no longer accept training solely by preceptorship in fulfillment of educational requirements for admission to examination. To be eligible for preceptorship thereafter the candidate must have had a minimum of one year formal residency training in an institution approved by the board for residency training in obstetrics and/or gynecology.

After the above date, candidates who propose preceptorship training must notify the secretary of the board of such intent and request an application form. When this has been completed, signed by the preceptor and preceptee and returned to the secretary, it will be submitted (as has long been true of residency training programs) to the residency training committee of the board for their decision.

If the program is approved the preceptor must supervise closely the candidate's work and keep an informative record of the candidate's performance. The preceptor and the preceptee shall report in writing to the secretary of the board at the end of each six months of preceptorship, outlining the progress of the training program. This information will be placed in the candidate's application for admission to examination in order that it may be evaluated by the credentials committee.

As a general rule each year of preceptor training will receive a six months' credit toward the total of three years of training necessary for admission to examination. As is the case with candidates whose training has been entirely by formal residency, each application will be evaluated finally by the credentials committee.

An acceptable preceptor preferably shall be one certified by the American Board of Obstetrics and Gynecology and must have been certified for a minimum of five years. Fellowship in the American College of Surgeons or long experience and established reputation as an obstetrician-gynecologist without either of the above qualifications may qualify the preceptor.

Preceptor and preceptee must work in a hospital approved by the Joint Commission on Accreditation of Hospitals.

The post-training practice requirements cannot be carried on concurrently with preceptorship training.

CERTIFICATION

Each certificate granted or issued does not of itself confer or purport to confer upon any person any degree or legal qualifications, privileges, or license to practice obstetrics or gynecology, nor does the board intend in any way to interfere with or limit the professional activities of any duly licensed physician who is not certified by this board. The chief aim of the board is to standardize qualification for specialists in obstetrics and gynecology, and to certify as specialists those who voluntarily appear before the board for such recognition and certification according to its regulations and requirements.

The board does not subscribe to any hospital rule that certification is to be required for medical appointments especially in ranks lower than chief or senior staff of hospitals, or associate professor in schools of medicine, for the obvious reason that such appointments constitute desirable specialist training.

Even though certification or its full equivalent may be considered a desirable requisite to appointment in key positions, as on the senior or chief staff, particularly of hospitals expecting to conduct approved services for training of residents, it was never intended by this board that certification should be required by any hospital as a prerequisite to appointment, especially in such lesser positions.

AMERICAN BOARD OF OPHTHALMOLOGY

Francis H. Adler, Chairman, Philadelphia.
Brittain F. Payne, Vice-Chairman, New York.
William L. Benedict, Consultant, Rochester, Minn.
Conrad Berens, Consultant, New York.
Frederick C. Cordes, Consultant, San Francisco.
Georgiana D. Theobald, Consultant, Oak Park, Ill.
James H. Allen, New Orleans.
Walter S. Atkinson, Watertown, N. Y.
Alson E. Braley, Iowa City.
Gordon M. Bruce, New York.
Paul A. Chandler, Boston.
F. Bruce Fralick, Ann Arbor, Mich.
Michael J. Hogan, San Francisco.
John S. McGavic, Bryn Mawr, Pa.
Kenneth C. Swan, Portland, Ore.
Merrill J. King, Secretary-Treasurer, Rockland, Maine.
Miss Lea M. Stelzer, Registrar, 56 Ivie Road, Cape Cottage, Maine.

Address all communications to the American Board of Ophthalmology, Cape Cottage, Maine.

NO DEGREES OR LEGAL RESTRICTIONS

Each certificate granted or issued does not of itself confer or purport to confer on any person any degree or legal qualifications, privileges, or license to practice ophthalmology, nor does the board intend in any way to interfere with or limit the professional activities of any duly licensed physician. Its chief aim is to elevate the standards of qualification for specialists in ophthalmology and to certify as specialists doctors of medicine who appear before the board for such recognition and certification, according to its requirements and regulations.

REQUIREMENTS

All candidates must comply with current board regulations regardless of time of filing application. The board, acting as a committee, reserves the right to reject an applicant for any reason deemed advisable and without stating the same, and the action of the board shall be final. Many candidates write the secretary outlining their training and asking for an estimate of their status and the further training required. The board's requirements are published to provide this information, and any candidate should be able to estimate his eligibility after studying these requirements. Individual officers or members of the board cannot and will not make such estimates. They will be made only by the committee on requirements, upon submission of the application for examination and the payment of the registration fee which must accompany it. Personal interviews with officers and members of the board should not be requested at any time.

PREREQUISITES

1. High ethical and professional standing.

2. Full citizenship in the country where the candidate practices. (Limited to countries of North and South America, their possessions and territories, and the Philippine Republic.)

3. A degree from a medical school of high standing, satisfactory to the board and approved by the Council on Medical Education and Hospitals of the American Medical Association. An applicant whose training has been received outside of the United States and Canada must present credentials satisfactory to the board and is required to have the certificate of the National Board of Medical Examiners if he has been in practice less than 10 years.

4. Completion of an internship of not less than one year in a hospital approved by the same Council.

5. Completion, by the time of the written qualifying test, of not less than 36 months (a total of 60 months is required of candidates practicing both ophthalmology and otolaryngology) of combined study, training, and practice of ophthalmology in approved medical schools, hospitals, clinics, dispensaries, laboratories, preceptorships, and private practice.

6. Effective Jan. 1, 1957:

(*a*) Licensure in the state, province, or country where the candidate practices.

(*b*) Individuals who have completed three years of formal ophthalmological training (residency and basic science courses) will be eligible to apply for the written qualifying test after completion of one year of practice or one year of institutional work. All other individuals (with less formal training) will be eligible to apply for the written test after 60 months in ophthalmology or 72 months of combined ophthalmology and otolaryngology. A basic course is recognized as equivalent in time to residency training.

GENERAL REQUIREMENTS FOR ALL CANDIDATES

1. Application forms must be filled out completely and accurately. Letters of endorsement, together with any other required credentials, must be sent to the secretary's office before the deadline date.
2. Fee of $100 remitted with application.
3. A list of papers or books published.
4. Written qualifying test.
5. Practical examination.
6. Special review of ophthalmic surgery.
7. Membership in the American Medical Association or such other societies as are recognized for the purpose by the Council on Medical Education and Hospitals of the American Medical Association.

FEES

For written test and original examination, $100 (as mentioned above).

Repeating written qualifying test, $65.

Repeating practical examination, $65.

Single conditions, written or practical, $25.

Two or more conditions, $35.

Written qualifying test must be taken within three years of date of application. Thereafter new application and fee are required.

The fees have been carefully computed on a basis of cost of examinations and are used entirely for administrative expenses. Examiners serve without compensation other than actual expenses.

SPECIAL TRAINING

This shall include:

1. Graduate study of the basic medical sciences which are fundamental to the intelligent practice of ophthalmology, particularly: anatomy, histology, embryology, optics, physiological optics, visual physiology and psychology, pathology, bacteriology, pharmacology, disorders of ocular motility and binocular vision, perimetry, and in the skillful adjustment and use of instruments such as the ophthalmoscope, retinoscope, slit lamp, and microscope. Mere factual knowledge is not sufficient; the candidate must have had training in the application of these subjects and in their use in clinical ophthalmology, especially in refraction.

2. Active clinical experience in approved hospitals, clinics, dispensaries, and private practice. Library and laboratory facilities should be utilized for intensive study of cases.

The subject matter to be covered under 1 and 2 is outlined in the syllabus prepared by the board.

These requirements may be met in various ways:

BASIC STUDIES

Anatomy and histology of the normal eye
Embryology and developmental abnormalities
Biochemistry
Pathology
Microbiology and immunology
Optics and physiological optics
Ocular physiology
Medical ophthalmology
Pharmacology
Neuro-ophthalmology
Principles of ophthalmic surgery

These may be covered by:

A. *Graduate Study.*—By a curricular course in the basic sciences related to ophthalmology in an approved graduate medical school.

B. *Postgraduate Study.*—By courses in individual basic sciences related to ophthalmology as given at various approved institutions. The Home Study Course of the American Academy of Ophthalmology and Otolaryngology is recommended.

C. *Residency.*—By advanced study of these subjects during a residency and by correlation of the principles involved with clinical problems.

D. *Research, Fundamental and Clinical.*—By the detailed study, under supervision or as assistant to an experienced research worker, of some problem or topic which brings the basic sciences into direct relation with the concrete clinical problem.

CLINICAL EXPERIENCE

A. By residency in an approved hospital. The most desirable of these residencies have regular lectures covering the entire field of clinical ophthalmology and of the basic subjects as applied in clinical practice. Many of these have seminars at which residents report cases which they have carefully worked up. These are discussed by the other residents and by the staff, and the method of presentation as well as the subject matter, is critically considered.

B. By residencies in hospitals in which regular instruction by lectures and quizzes and seminars is not available. The syllabus issued by the board will guide the resident in his selection of topics to be studied.

C. By fellowships in ophthalmology.

D. By preceptorship with a well-trained and critical ophthalmologist.

E. After completing a residency it is of great advantage to secure a position in a clinic as fellow or assistant. This may require only part-time work, but due credit will be given. Its value to the student depends on how much study he puts into it and on how competent his seniors are.

F. Research under competent critical and sympathetic supervision will give firsthand insight into (1) the methods whereby old knowledge was and new knowledge is acquired and (2) the pitfalls that accompany attempts to enlarge the sphere of knowledge. Only in this way can the candidate evaluate basic facts in the intelligent critical way which is expected of the specialist in practice.

G. The candidate who cannot secure the type of residency he desires should not despair, for his progress depends far more on how he uses his opportunities than on the opportunities themselves.

MILITARY SERVICE

Credit for military service is given on an individual basis, each case being considered on its own merits and the amount of credit allowed is determined by the board when the information is submitted with the application.

WRITTEN QUALIFYING TEST

Before being accepted for examination, candidates are given a written test to ascertain their qualifications. The questions may cover any part of ophthalmology and are especially devoted to the basic studies as listed above. The written test will be given in several principal cities at the same time. Choice of cities is determined largely by the geographical distribution of candidates. Candidates found acceptable will be notified to appear for a subsequent practical and clinical examination in ophthalmology.

EXAMINATIONS

Examinations usually are held annually at or near the time and place of the meeting of the American Medical Association; also at other times and places at the discretion of the board, depending on the number of applications from any region.

The board reserves the right to limit the number of candidates to be admitted to any scheduled practical examination.

Candidates must be examined in all subjects listed in the sections titled Basic Studies and Practical and Clinical Examination.

PRACTICAL AND CLINICAL EXAMINATION

The subjects of the practical examination are as follows: (1) External Diseases, (2) Ophthalmoscopy, (3) Histopathology, (4) Refraction, (5) Motility, (6) Ophthalmic Surgery, and (7) Perimetry.

1. *External Diseases of the Eye and Adnexa.*—Various methods of examination, diagnoses, and treatment.

2. *Ophthalmoscopy.*—Patients will be examined by the candidate and the findings described or drawn. A candidate is required to bring his own ophthalmoscope.

3. *Pathology.*—The candidate will demonstrate familiarity with general clinical pathology as well as the etiology, pathology, and bacteriology of diseases of the eye. He will be asked to examine microscopic slides and to recognize normal and pathological histology of the eye.

4. *Refraction.*—A candidate will examine patients and show mastery of various methods, and of the principles of refraction and of retinoscopy. He should bring his own retinoscope.

5. *Motility.*—The candidate will demonstrate on patients his familiarity with routine methods of examination and diagnosis.

6. *Ophthalmic Surgery.*—Examination of surgical patients and discussion on principles of ophthalmic surgery.

7. *Perimetry.*—The candidate will be given an opportunity to examine patients by use of the arc perimeter, the tangent screen, and the stereocampimeter. He may also be required to interpret charted fields.

SPECIAL REVIEW OF SURGICAL CASES

The board now requires of all candidates a list of ophthalmic operations performed within two years prior to examination. This list is to be presented with application.

The operations should be listed in groups of each type of surgery. The numbers of operations in each group must be totaled and the total number of all operations shown. This list must contain the following data:

1. Date.

2. Condition or conditions for which operation was performed. Complications during hospitalization.

3. Name and character of operation.

4. Identification by hospital or clinic number, or the name of a consultant or conferee, who was present at the time of operation.

Circumstances that prevent any candidate from fulfilling this requirement should be fully explained, with detailed statement of candidate's surgical experience.

CERTIFICATION

The decision of the board is final as to the candidate's passing, failure, or partial failure. The final action of the board is based on the candidate's ethical and professional record, training and attainments, as well as on the results of his formal examinations.

Certified ophthalmologists should refer to themselves as diplomates of the American Board of Ophthalmology. (There are only 12 members of the board and these are elected from the 3 component societies.)

REEXAMINATION

Candidates may be reexamined as often as they desire on satisfactory evidence of adequate additional preparation and payment of reexamination fee. When a candidate is conditioned in one or more subjects the committee on examinations shall decide on the merits of the case and the length of time that must elapse before reexamination in these subjects. A minimum of two years additional preparation is required of candidates who fail in all subjects. The board may, at its discretion, deny the candidate the privilege of reexamination.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY

Harold A. Sofield, President, Chicago.
William M. Roberts, Vice-President, Gastonia, N. C.
Hugh Smith, Memphis, Tenn.
William T. Green, Boston.
Clarence H. Heyman, Cleveland.
Don E. King, San Francisco.
Mather Ceveland, New York.
Charles J. Frankel, Charlottesville, Va.
George J. Garceau, Indianapolis.
Harold A. Sofield, Secretary-Treasurer, 116 S. Michigan Ave., Chicago 3.

Advisory Council

Ralph K. Ghormley, Rochester, Minn.
Allen F. Voshell, Baltimore.
Francis M. McKeever, Los Angeles.
Guy A. Caldwell, New Orleans.

GENERAL ELIGIBILITY REQUIREMENTS

1. Satisfactory moral and ethical standing in the profession.

2. Graduation with a degree of doctor of medicine from a medical school of the United States or Canada, recognized by the Council on Medical Education and Hospitals of the American Medical Association, or graduation from a foreign school on the approved list of the afore-mentioned Council.

3. Completion of an internship of not less than one year in a hospital approved at that time by the Council on Medical Education and Hospitals of the American Medical Association or, if trained in foreign countries, in institutions considered satisfactory by the American Board of Orthopaedic Surgery.

4. Completion of one year of resident training in general surgery in a hospital approved by the Council on Medical Education and Hospitals of the American Medical Association or substitute training in general surgery considered satisfactory by the American Board of Orthopaedic Surgery. The minimum of one year of training in general surgery is in addition to the minimum of one year of internship. This requirement may be fulfilled by substituting a second year of internship, by time spent in research, by time spent on a service in which there is an overlap of interest with orthopedic surgery, by a fourth year of approved orthopedic resident training, or by surgical work in private or military life.

5. Completion of formal requirements for part 1 or part 2 examinations. These formal requirements can be satisfied only by training in one or two categories: (*a*) resident orthopedic training and (*b*) preceptorship training.

Applicants may not be admitted to examinations, or be certified, on the basis of extensive specialized practice and/or teaching appointments and/or many short unapproved courses.

6. Restriction of practice to orthopedic surgery.

REQUIREMENTS FOR PART 1 EXAMINATIONS

1. Completion of and compliance with afore-mentioned general eligibility requirements.

2. Citizenship in the United States or Canada, or possession of citizenship papers showing intent to become a full citizen.

3. Following completion of a year of internship, satisfactory completion of a minimum of one year of general surgical training, or its substitute, plus (*a*) two years of approved training in orthopedic surgery under a program of resident training, or (*b*) completion of a minimum of five years of orthopedic training under a preceptorship program.

4. Evidence of competence in training.

5. Approval for examination by the committee on eligibility of The American Board of Orthopaedic Surgery.

REQUIREMENTS FOR PART 2 EXAMINATIONS

1. Successful completion of part 1 examinations.

2. Full citizenship in the United States or Canada.

3. License to practice in the United States or Canada.

4. Satisfactory completion of a minimum of three years of approved resident training in orthopedic surgery, plus a minimum of two subsequent years of practice period for applicants trained under resident orthopedic training programs.

5. Satisfactory completion of a minimum of five years of practice period for applicants trained under preceptorship programs.

6. Evidence of competence in practice.

7. Approval for examination by the committee on eligibility of the American Board of Orthopaedic Surgery.

APPLICATION AND EXAMINATION FEE SCHEDULE

1. Application for part 1, fee $15, not returnable.

2. Examination, part 1, fee $35, payable only if approved for examination. Approved candidates failing to appear for scheduled examinations forfeit fees.

3. Application for part 2, fee $15, not returnable.

4. Examination, part 2, fee $50, payable only if approved for examination. Approved candidates failing to appear for scheduled examinations forfeit fees.

5. Reexamination, part 1, fee $35; for part 2, fee $50. No application fee is required for reexamination.

APPLICATIONS

1. Applications for part 1 examinations must be received in the office of the secretary of the board before Nov. 30 of the year preceding the examinations.

2. Applications for part 2 examinations must be received in the office of the secretary of the board before Aug. 15 of the year preceding the examinations.

3. Notices of acceptance for admission to the part 1 examinations are mailed to eligible candidates during the month of February in the year of the examinations.

4. Notices of acceptance for admission to part 2 examinations are mailed to eligible candidates during the month of November in the year preceding the examinations.

5. Questions of eligibility for examinations are decided by the committee on eligibility of the board. This committee meets twice yearly. The secretary is not empowered to rule on questions of eligibility.

6. The life of an application is three years. After this time a new application and application fee must be submitted.

EXAMINATIONS

1. Part 1 examinations are held once yearly, usually in April or May, in various centers in the United States.

2. Part 2 examinations are held once yearly, usually in one center, immediately preceding the meeting of the American Academy of Orthopaedic Surgeons.

3. The locations and dates of coming examinations are announced in THE JOURNAL of the American Medical Association and the *Journal of Bone and Joint Surgery*.

CERTIFICATION

1. Applicants who successfully pass part 1 examinations will receive no certificate but will be notified by letter by the secretary.

2. Applicants who successfully pass part 2 examinations receive a certificate of the board, which states that they have been found qualified to practice the specialty of orthopedic surgery in those fields in which they have been trained and examined.

3. Candidates obtaining certification without training and examination in children's orthopedic surgery may subsequently add certification in children's orthopedic surgery by completing a minimum of one year of approved resident orthopedic training in children's orthopedic surgery and successfully passing examination in that field. A practice period of one year is required following completion of resident training, prior to examination for additional certification.

APPROVED RESIDENCIES

1. In the United States, resident training must be taken in institutions approved for resident training in orthopedic surgery by the Council on Medical Education and Hospitals of the American Medical Association. All approved institutions are listed yearly in the Internship and Residency Number of THE JOURNAL. Lists may be obtained from the American Medical Association and are not obtainable from the board.

2. The integral parts of approved residencies are designated in lists by the following symbols: A—adult orthopedic surgery; C—children's orthopedic surgery; F—fracture surgery; and S—basic science training. Approved lengths of training in institutions is also designated.

3. Candidates electing an additional year of training in adult orthopedic surgery and fracture surgery in lieu of a year in children's orthopedic surgery may satisfy requirements by continuing their training beyond the designated approved length of time in institutions approved for adult orthopedic surgery or adult orthopedic surgery and fractures.

4. Credit for resident training is not retroactive. Candidates must receive resident training in institutions during periods that such institutions are on the approved list. If candidates are in training at institutions at the time that such institutions become approved, resident training credit may be granted from the start of the training period provided that the program is judged to have been satisfactory.

5. Candidates in resident training, or possessing signed contracts for future resident training in institutions which become disapproved, either in whole or part, receive resident training credit for the entire period during which their contracts are in force.

6. The term "fellow" is considered synonymous with "resident" when the position occupied and the work performed is equal in all functions. Fellowships in institutions having residents, in which training and responsibilities are not equal, are not credited as resident training.

7. Institutions approved for resident training in orthopedic surgery by the Council on Medical Education and Hospitals of the American Medical Association may, with prior acceptance by the American Board of Orthopaedic Surgery and notification to the Council, utilize the training facilities of institutions not individually approved for resident training by the aforementioned Council, provided that: (*a*) the training supplements services in the same categories in which the institution responsible for training is approved by the Council, (*b*) the resident spends at least half of the minimum required time in each category of training in institutions approved by the Council.

8. Foreign residencies must satisfy the American Board of Orthopaedic Surgery.

9. Application for approval of the training facilities of any institution must be made to the Council on Medical Education and Hospitals of the American Medical Association, and inspection of such facilities is made by representatives of the Council. Final approval is a joint function of the Council and the American Board of Orthopaedic Surgery.

REQUIREMENTS OF RESIDENT ORTHOPEDIC TRAINING

1. Institutions approved for full three year programs including all parts of the training requirements may integrate all parts so that they are given concurrently.

2. Institutions now approved for less than three years of orthopedic resident training should arrange with other approved institutions to provide complete three year programs for all residents.

3. The minimum requirements of resident orthopedic training are as follows: (*a*) one year of training in adult orthopedic surgery, (*b*) six months of training in the basic sciences, (*c*) six months of training in fracture surgery, and (*d*) one year of training in children's orthopedic surgery or, if elected, an additional year of training in adult orthopedic surgery and fracture training in place of training in children's orthopedic surgery.

4. Candidates who elect an additional year of training in adult orthopedic and fracture surgery instead of a year in children's orthopedic surgery may satisfy the requirements by taking the additional year of training in adult orthopedic surgery or six months of adult orthopedic surgery and six month of fracture surgery, but may not take the entire year of training in fracture surgery.

5. Training in adult and children's orthopedic surgery mus include observation and first hand experience in diagnosis, treatment, operative and postoperative care of orthopedic problems

6. Training in fracture surgery must include observation an first hand experience in diagnosis, treatment, operative and postoperative care of recent and old fractures.

7. Training in the basic sciences must instill a sound knowledge of anatomy, pathology, physiology, bacteriology, an biochemistry as these basic sciences apply to orthopedic surgery

8. Candidates may complete the training requirements b training in several approved institutions provided that all th aforementioned minimum requirements are satisfied on approve services.

9. *No training period of less than six consecutive* months i one institution may be credited toward resident training requirements, except a few short courses on the board's approved lis and recognized supplementary services of approved institutions

10. *Candidates in resident training may not engage* in privat practice.

11. Candidates in resident orthopedic training must receiv their training in institutions and may not receive credit for tim spent assisting in private office practice, which is considered a preceptorship training.

REQUIREMENTS OF PRECEPTORSHIP TRAINING

1. The preceptor must possess certification by the American Board of Orthopaedic Surgery.

2. The practice of the preceptor must be extensive enough to give the candidate experience in all phases of orthopedic practice.

3. The preceptor must devote special periods of time each week, outside of the routine hours employed in hospitals and office practice, to assist the candidate with organized courses of study similar to those received during resident training.

4. If facilities and instruction in the related basic sciences are not available, the candidate must spend a minimum of six months as a student in an institution approved for basic science training in orthopedic surgery.

5. The candidate in preceptorship training must spend six months in an institution approved for basic science training in orthopedic surgery. No credit for children's training will be allowed unless the preceptor is on the active staff of an institution approved by the Council for resident training in children's orthopedic surgery. The candidate must train as a full-time assistant to the preceptor and may not maintain a separate office or engage in individual practice.

6. The minimum training period in orthopedic surgery under the preceptorship program is five years in addition to the one year of resident training in general surgery or its substitute, after which time the candidate may file application for part 1 examinations.

7. The minimum practice period required for candidates trained under the preceptorship program is five years, after which time the candidate may file application for part 2 examinations. This makes a minimum total of 10 years from the start of orthopedic training to eligibility for part 2 examinations.

8. The practice period may be satisfied in individual private practice or in assistantship or partnership.

9. Candidates who combine preceptorship training with approved resident training receive credit for the preceptorship portion of their training only if it totals a minimum of two years. Two years of preceptorship training are credited as the equivalent of one year of resident training. The practice period requirement is likewise evaluated so that three years of practice are required if the candidate submits two years of preceptorship and two years of resident training, and four years of practice are required if four years of preceptorship and one year of resident training are submitted.

SEQUENCE OF EXAMINATIONS AND PRACTICE REQUIREMENTS

1. No person may take part 2 examinations until after successful completion of part 1 examinations.

2. Successful completion of part 1 examinations in no way obligates the board to declare a candidate eligible for part 2 examinations.

3. Regardless of how extensive or prolonged a practice a candidate may have had prior to completing the training requirements, such time may not be credited toward practice requirements. All practice requirements must be satisfied subsequent to completion of training requirements.

4. Candidates may not be admitted to examinations on the basis of prolonged practice but must qualify on the basis of formal training in one of the categories previously detailed.

PRACTICE REQUIREMENTS

1. Candidates must maintain high ethical and professional standards.

2. Candidates must strive to increase their scientific knowledge.

3. Candidates must limit their practice to orthopedic surgery.

4. Candidates who have had no approved training in children's orthopedic surgery must confine their practice to fracture and adult orthopedic surgery.

5. Candidates trained in resident orthopedic training are required to complete a minimum of two years of orthopedic practice subsequent to the completion of their formal training before becoming eligible for part 2 examinations.

6. Candidates in private or institutional practice must spend a minimum of 14 months in one locality immediately prior to application in order that practice may be properly evaluated.

7. Candidates employed full time in institutions may satisfy practice requirements by serving a minimum of two years, but minimum requirements may not be satisfied by mixing full-time institutional work with preceding or subsequent time in private practice.

8. Candidates trained by preceptorship are required to complete a minimum of five years of orthopedic practice before becoming eligible for part 2 examinations. The practice period may be independent of the preceptor.

METHOD OF EXAMINATION

1. Part 1 examinations consist of a written examination and oral examinations. Material covered includes fundamental surgical principles, elementary fracture and orthopedic procedures, history-taking, and physical examinations as well as those parts of anatomy, pathology, physiology, and biochemistry related to orthopedic surgery. The oral examinations consist of five parts: (*a*) anatomy, (*b*) pathology, (*c*) physiology and biochemistry, (*d*) surgery, and (*e*) fractures and orthopedic surgery.

2. Part 2 examinations consist of a written examination and oral examinations. Material covered includes advanced work in all phases of orthopedic surgery. The oral examinations consist of five parts: (*a*) anatomy, (*b*) pathology, (*c*) children's orthopedic surgery, (*d*) fractures, and (*e*) adult orthopedic surgery.

3. Candidates who have not had approved training in children's orthopedic surgery will not be examined in that branch of orthopedic surgery.

4. Candidates are notified by letter as to whether they passed or failed in the examinations. No information regarding results is available until such letters are mailed.

5. Results of integral parts of examinations are not available to either candidates or diplomates of the board.

6. Candidates who have passed part 1 examinations are required to take part 2 examinations within a 10 year subsequent period. If there is a lapse of more than 10 years, candidates must repeat part 1 examinations and must then become eligible by the requirements then in force.

REEXAMINATIONS

1. Applicants who fail to pass part 1 or part 2 examinations may be reexamined a second or third time in each part, but must pay the prescribed examination fee each time of reexamination.

2. Applicants who fail to appear for second and, if necessary, third reexaminations within three years after first failure must submit new applications with the appropriate fees.

3. After three successive failures in part 1 or part 2 examinations, applicants must present evidence of additional orthopedic training satisfactory to the board before submitting new applications.

MILITARY SERVICE

1. Medical officers who have elected service in the military forces as their life careers compete for certification on the same basis as do physicians in civilian practice.

2. Physicians who served for a minimum of one year in the military forces during the war years, between Jan. 1, 1941, and July 1, 1946, are granted a bonus of one year of practice credit, provided that the same time is not used for resident training credit.

3. Applicants who served in military hospitals whose service is judged by the board to have been equal to that of approved resident orthopedic training may be granted a maximum credit of one year of resident orthopedic training. Applicants requesting such credit must submit completed "Professional Training Records."

4. No applicant may be granted more than one year of resident training credit and one year of practice credit for military service during the war years.

5. Medical officers assigned to civilian institutions on the approved list for resident orthopedic training receive the same credit as do civilian candidates.

6. Medical officers who have elected service in the military forces as their life careers must satisfy the practice requirements by military assignments in which their duties are limited to the practice of orthopedic surgery.

RECORDS OF SURGICAL CASES AND INSPECTIONS

1. Records of a specified number of consecutive surgical cases may be requested by the board in order to evaluate properly the work of an applicant.

2. A representative of the board may visit a community in order to evaluate properly the work of an applicant.

AMERICAN BOARD OF OTOLARYNGOLOGY

Officers of the Board

Frederick T. Hill, President, Waterville, Maine.
Gordon D. Hoople, Vice-President, Syracuse, N. Y.
Dean M. Lierle, Secretary-Treasurer, University Hospitals, Iowa City.

Senior Counselors

George M. Coates, Philadelphia.
Ralph A. Fenton, Portland, Ore.
Gordon F. Harkness, Davenport, Iowa.
Carl H. McCaskey, Indianapolis.
W. E. Sauer, St. Louis.
Ernest M. Seydell, Wichita, Kan.
Frank R. Spencer, Boulder, Colo.
Fletcher D. Woodward, Charlottesville, Va.

Board of Directors

Lawrence R. Boies, Minneapolis.
Louis H. Clerf, Philadelphia.
Daniel S. Cunning, New York.
Russell M. Decker, Pasadena, Calif.
Lyman H. Heine, Fremont, Neb.
Frederick T. Hill, Waterville, Maine.
Gordon D. Hoople, Syracuse, N. Y.
Percy E. Ireland, Toronto, Canada.
Francis L. Lederer, Chicago.
Francis E. LeJeune, New Orleans.
Dean M. Lierle, Iowa City.
H. I. Lillie, Rochester, Minn.
John R. Lindsay, Chicago.
Bernard J. McMahon, St. Louis.
William J. McNally, Montreal, Canada.
James H. Maxwell, Ann Arbor, Mich.
Philip E. Meltzer, Boston.
Lewis F. Morrison, San Francisco.
Werner Mueller, Boston.
C. Stewart Nash, Rochester, N. Y.
Henry B. Orton, Newark, N. J.
Arthur W. Proetz, St. Louis.
LeRoy A. Schall, Boston.
Harry P. Schenck, Philadelphia.
O. E. Van Alyea, Chicago.

Assistant

George F. Reed, Boston.

GENERAL REQUIREMENTS

The following general qualifications of candidates for examination are required by the board:

1. A candidate must be a citizen of the United States or the Dominion of Canada.

   (a) A candidate must have been a graduate for five years or more of a medical school approved by the Council on Medical Education and Hospitals of the American Medical Association.

   (b) A candidate must be of known good moral character and be ethical in his professional relationships.

   (c) A candidate trained in a foreign country must be able to give proof of medical and graduate training comparable to the requirements of the board.

   (d) A candidate from the United States or the Dominion of Canada must be a member of the American Medical Association or of the Canadian Medical Association respectively or other such medical societies of equal standing as are recognized by the Council on Medical Education and Hospitals of the American Medical Association.

2. Candidates from foreign countries who have received their training in otolaryngology in the United States are eligible for examination at the discretion of the board, providing they show proof that they are permanent residents and citizens of their respective foreign countries and provided they meet the general academic requirements of the board.

SPECIAL REQUIREMENTS

1. A candidate must have had a general internship of at least one year in a hospital approved by the Council on Medical Education and Hospitals of the American Medical Association.

2. A candidate must be proficient in the applied basic sciences, fundamental to the intelligent practice of otolaryngology. These include anatomy of the ear, nose, and throat, neck chest, esophagus and nervous system, gross pathology and histopathology, bacteriology, physiology, didactic otolaryngology and the general fundamentals of surgery. (This requirement may be fulfilled in a residency or fellowship service or in an approved organized postgraduate course.)

3. In addition to the general internship, the required clinical training in otolaryngology may have been acquired in any of the following ways:

   (a) A three years' approved residency or fellowship in otolaryngology approved by the Council on Medical Education and Hospitals of the American Medical Association.

   (b) A four years' approved residency or fellowship in otolaryngology and ophthalmology approved by the Council on Medical Education and Hospitals of the American Medical Association, provided one half of the training has been in otolaryngology.

   (c) A two years' approved residency or fellowship in otolaryngology or a three years' approved combined residency or fellowship in otolaryngology and ophthalmology, provided two years have been in otolaryngology and have been preceded by at least one year's approved residency training in surgery or medicine, or by an additional year in an approved internship.*

4. In exceptional circumstances certain candidates who cannot meet all of the above requirements may be accepted for examination on recommendation of the credentials committee, substantiated by action of the board.

5. At least one year must be spent in private, group, or institutional practice of otolaryngology after the period of special training. This requirement may be waived in cases of candidates of foreign countries who are permanent residents and citizens of their respective countries and who are returning there for the practice of otolaryngology. Should such a candidate pass the examination the certificate of the board will be withheld until the board has been furnished evidence that the candidate has spent one year in the practice of otolaryngology.

6. A candidate may be qualified for examination, at the discretion of the American Board of Otolaryngology, if in addition to the General Requirements and Special Requirements, no. 1 and 2, he has limited his practice to otolaryngology for seven years in association with a hospital staff approved by the Council on Medical Education and Hospitals of the American Medical Association.

7. A physician who limits himself exclusively to the practice of peroral endoscopy may be granted limited certification in this field by the American Board of Otolaryngology irrespective of certification in any other specialty. Limited certification will be granted provided the candidate has spent not less than one year of training in a hospital approved for endoscopic teaching and has passed successfully examinations in the basic sciences as they pertain to this field, and didactic and clinical examinations covering diseases of the larynx, pharynx, neck, esophagus, stomach, tracheobronchial tree, lungs and mediastinum and certain aspects of cardiovascular disease as they pertain to peroral endoscopy. A limited certificate by the American Board of Otolaryngology will not be issued to physicians who have been certified in a specialty that employs peroral endoscopy in diagnosis and/or

---

* See Standards for Residencies in Otolaryngology published by the merican Medical Association.

treatment because his major interest is in that specialty, not in endoscopy.

All candidates must comply with current board regulations, regardless of the time of filing application.

APPLICATION AND FEES

1. Application must be made in duplicate on special blanks procured from the secretary. The completed application blanks must be returned to the secretary, together with the other required credentials, at least 120 days in advance of the examination at which the candidate desires to appear.

2. The applications must be accompanied by two small photographs of the candidate, together with verification of the period of enrollment from the institutions where training in otolaryngology was obtained, and the names of two or more otolaryngologists, preferably diplomates of the board, from the vicinity of the candidate's place of residency, to be used as references.

3. The fee for the examination is $150. Of this sum $75 must accompany the application, of which $50 shall be returned if candidate is not accepted for examination. No application will be acted on until the $75 application fee is received. The remaining $75 of the total examination fee of $150 must be paid to the secretary on notification that the candidate has been accepted. A reexamination fee of $75 is required of candidates conditioned in one or more subjects.

4. The fees have been carefully computed on a basis of cost of examinations and are used entirely for administrative expenses. Examiners serve without compensation other than actual expense.

5. The application remains valid for three years. An applicant must appear for examination within this time or forfeit the fee.

6. Candidates whose credentials have been found satisfactory and who meet the requirements of the board will be notified 90 days prior to the date of examination. The number of candidates who can be admitted to any one examination is limited. Due to a large number of applications on file, delay in assignment for examination may be inevitable. Appointments will be given in the order applications are accepted and on payment of the balance of the examination fee.

7. The board, acting as a committee of the whole, reserves the right to reject an applicant for any reason deemed advisable and without stating the same, and the action of the board shall be final.

EXAMINATION

Examinations will be held at such time and place as the judgment of the board may dictate. Advance notice of examinations will be given in THE JOURNAL of the American Medical Association and the several special journals devoted to otolaryngology. Insofar as is possible these will be held biannually at, or near, the time and place of meeting of the American Medical Association, or special societies, and of the American Academy of Ophthalmology and Otolaryngology. The examinations cover from two to four days.

Scope.—This examination encompasses all phases of otolaryngology and peroral endoscopy, including maxillofacial surgery, and surgery of the neck, excluding the thyroid.

The type of examination is as follows:

1. Clinical, covering the actual handling of patients, including history-taking, physical and functional examinations, the use of laboratory and x-ray findings, and a discussion of differential diagnosis.

2. Didactic, oral examinations covering all phases of otolaryngology.

3. Gross and microscopic pathology.

4. A written examination may be included when the board deems this advisable.

REEXAMINATION

A candidate who is conditioned in examination may be admitted to a subsequent examination after one year and within the three year period dating from his application on payment of an additional fee of $75, and 120 days' notice of intention to appear is required.

AMERICAN BOARD OF PATHOLOGY

JAMES B. MCNAUGHT, President, Denver.
SHIELDS WARREN, Vice-President, Boston.
ROGER BAKER, Durham, N. C.
ISRAEL DAVIDSOHN, Chicago.
A. S. GIORDANO, South Bend, Ind.
JAMES W. KERNOHAN, Rochester, Minn.
DOUGLAS MACFADYEN, Chicago.
EDWARD B. SMITH, Indianapolis.
JAMES N. PATTERSON, Tampa, Fla.
S. BRANDT ROSE, Philadelphia.
JOHN R. SCHENKEN, Omaha.
WILLIAM B. WARTMAN, Secretary-Treasurer, 303 E. Chicago Ave., Chicago 11. (After Nov. 1, 1955, write to: EDWARD B. SMITH, Secretary-Treasurer, Indiana University Medical Center, 1040-1232 W. Michigan St., Indianapolis.)

GENERAL REQUIREMENTS

1. Satisfactory moral and ethical standing in the profession.

2. License to practice medicine or a certificate of the National Board of Medical Examiners.

3. The applicant must devote his time primarily and principally to the practice of pathology.

PROFESSIONAL EDUCATION

1. Graduation from a medical school in the United States approved by the Council on Medical Education and Hospitals of the American Medical Association, or graduation from a medical school in other countries acceptable to the board.

SPECIAL TRAINING AND EXPERIENCE

1. The board admits candidates to examinations who are otherwise eligible and who have had either of two following types of training and experience.

(*a*) After five years, if four of the five years have been in institutions approved by the Council on Medical Education and Hospitals of the American Medical Association or by the board; or

(*b*) After 11 years if none of the training and experience has been in institutions so approved.

2. The specific requirements for those acceptable after five years are as follows:

(*a*) Pathological anatomy only.

(1) Four years of supervised study and training in an institution approved for residency training in pathological anatomy by the Council on Medical Education and Hospitals of the American Medical Association or by the board. It is immaterial whether the candidate holds the title of resident or fellow or assistant. Candidates may, at their own election, substitute not to exceed 12 months of a straight or rotating clinical internship or a fellowship or instructorship in any of the preclinical departments of a university for one of the four years. In addition, time, not to exceed 12 months, spent in a department of pathology of an approved school of medicine after the completion of the second year of undergraduate study may be counted for full credit toward the four years.

(2) One additional year, which may be a continuation of the preceding or may be independent practice of pathological anatomy in a hospital approved by the American Medical Association or other institutions acceptable to the board.

(*b*) Clinical pathology only.

(1) Four years of supervised study and training in an institution approved for residency training in clinical pathology by the Council on Medical Education and Hospitals of the American Medical Association or by the board. It is immaterial whether the candidate holds the title of resident or fellow or assistant. Candidates may, at their own election, substitute not to exceed 12 months of a straight or rotating clinical internship or a fellowship or instructorship in any of the preclinical departments of a university, for one of the four years. Candidates holding also a master's or doctor's degree in a special field of clinical pathology (bacteriology, serology, chemistry, parasitology, or hematology) may obtain time credit for not more than 12 to 24 months toward the four years for this work,

regardless of whether it was taken before or after the medical degree. The evaluation of time credit will depend on how much of the broad field of clinical pathology was covered in the graduate work.

(2) One additional year, which may be a continuation of the *preceding or may be independent practice of clinical pathology* in a hospital approved by the American Medical Association or other institutions acceptable to the board.

(*c*) Pathological anatomy and clinical pathology.

(1) Four years of supervised study and training divided as follows: (*a*) two years of supervised study and training in pathological anatomy as outlined in the preceding paragraph 2-(*a*)-(1), (*b*) *two years of supervised study and training in clinical pathology* as outlined in the preceding paragraph 2-(*b*)-(1). Candidates declared eligible before July 1, 1953, may at their own election substitute one year (12 months) of a straight or rotating clinical internship for one year of this special training in clinical pathology. After July 1, 1953, all candidates applying for both pathological anatomy and clinical pathology will be required to have two years of supervised training in clinical pathology.

(2) One additional year, which may be a continuation of the preceding or may be independent practice of both pathological anatomy and clinical pathology in a hospital approved by the American Medical Association or other institutions acceptable to the board. After July 1, 1953, candidates who elect to claim credit for one year for a clinical internship must take this fifth year as supervised study and training in clinical pathology in institutions approved for residency training in clinical pathology by the Council on Medical Education and Hospitals of the American Medical Association or by the board. Candidates declared eligible after July 1, 1953, who do not take a clinical internship, may, after four years of training as outlined in 2-(1)-(*a*) and (*b*), spend the fifth year in independent practice in an institution or laboratory acceptable to the board.

NOTE: As outlined in the preceding paragraphs, the total time requirements of the board are unchanged after July 1, 1953, namely, five years of study or practice after graduation from medical school, with exceptions noted in sections 2-(*a*)-(1) and 2-(*b*)-(1).

3. The specific requirements for those acceptable after 11 years are as follows: (*a*) The practice of pathology under circumstances acceptable to the board for a period of not less than 11 years. At the election of the candidates, a period not to exceed one year of straight or rotating clinical internship may be substituted for one of the 11 years. For those candidates in this category who have had some special study and training in pathologic anatomy or clinical pathology acceptable under paragraphs 2-(*a*), (*b*), or (*c*), double time credit will be allowed. Thus, if a person has two years of acceptable supervised study and training, only seven years of practice are required.

SPECIAL QUALIFICATIONS

1. Prior to Dec. 31, 1947, the board at its discretion certified candidates without examination, if the following conditions were met as of July 1, 1939: (*a*) that the candidate has been for a period of five years of professorial rank in a department of pathology in an approved medical school; or (*b*) that the candidate had been practicing pathology for 10 years in a senior position in a hospital having an adequate department of pathology, approved by the Council on Medical Education and Hospitals of the American Medical Association or in an institution acceptable to the board.

CREDIT FOR MILITARY SERVICE

Credit may be allowed for training and experience in pathology in the federal services during the period July 1, 1940, to June 30, 1947. This credit for training or experience or both is given on an individual basis and will depend on the opportunity the applicant has had, as indicated by his or her medical service record in the specialty of pathology.

After July 1, 1947, credit for those military services will be given on the same basis as it is in civilian institutions, except that the rule in the preceding paragraph will not apply to reserve officers who continue on active duty or are called to active duty after that date.

SPECIAL FIELDS OF PATHOLOGY, CLINICAL CHEMISTRY, CLINICAL MICROBIOLOGY, HEMATOLOGY, AND NEUROPATHOLOGY (IN FORCE AFTER JULY 1, 1954)

The trustees of the American Board of Pathology have adopted the following requirements for certification in special fields of *pathology, effective July 1, 1954.*

Candidates who have met all general requirements and have had special training and experience that is acceptable to the board in a special field of pathological anatomy or clinica pathology may apply to the board for certification in that specia field. The board, at its discretion, may approve this applicatio and after the candidate has successfully passed a prescribe examination or has fulfilled certain *special qualifications* (se below, section D), will issue a certificate designating the specia field.

A. General Qualifications:

1. Satisfactory moral and ethical standing in the pr fession.
2. License to practice medicine or a certificate of tl National Board of Medical Examiners.
3. The applicant must devote his time primarily a principally to the practice of pathology or the speci field of pathology in which he is requesting certific tion.

B. Professional Education:

1. Graduation from a medical school in the United Stat approved by the Council on Medical Education a Hospitals of the American Medical Association graduation from a medical school in other countr acceptable to the board.

C. Special Training and Experience:

The board admits candidates to examination in spec *fields of pathology who are otherwise eligible* and w have had either of the following types of training:

1. Applicants already holding a certificate of the board clinical pathology or the combined certificate pathological anatomy and clinical pathology (qualification in clinical chemistry, clinical microbi ogy, and hematology), or in pathological anato (for qualification in neuropathology)—two additio years of supervised training in the special field their choice *in institutions* approved by the Cour on Medical Education and Hospitals of the Ameri Medical Association or by the board.
2. Applicants not holding a certificate in pathologi anatomy or clinical pathology—five years of train in the special field of their choice, provided four the five years have been in institutions approved the Council on Medical Education and Hospitals the American Medical Association or by the boa Candidates may, at their own *election*, substitute to exceed 12 months of a straight or rotating clini internship or a fellowship or instructorship in any the preclinical departments of a university for one *the four years.* The fifth year may be a continuati of supervised training or may be independent pr tice of the particular specialty in a hospital appro by the American Medical Association or in other stitutions acceptable to the board.

D. Special Qualifications—Certification Without Examinatio

Prior to Jan. 1, 1960, the board at its discretion m certify candidates without examination if the followi conditions have been met as of Jan. 1, 1955:

1. That the candidate has been for a period of five ye of professorial rank in the special field of his choi and in an approved medical school; or
2. That the candidate has been practicing his special for 10 years in a senior position in a hospital havi an adequate department in the special field, approv by the Council on Medical Education and Hospit of the American Medical Association, or in an ins tution acceptable to the board.

APPLICATION BLANK AND FEE

Application must be made on the special form that may be procured from the secretary and forwarded with other required credentials and the application fee. An application cannot be given consideration by the board unless it is accompanied by the application fee.

The application or examination fee for candidates is $60. If the candidate fails in his examination he will be admitted to a second examination after one year. The applicant must pay an additional fee of $40 before a second examination will be given.

The application fee of $60 has been determined after careful consideration and is based on actual estimates of the expenses of examination and administration. None of the board members receive any compensation for their services except actual expenses incurred.

If the applicant, for any reason, is deemed ineligible for examination by the board, his fee will be returned; however, the application fee is not returnable after the candidate has officially been accepted for examination and notified to report for the examination.

EXAMINATIONS

Written and oral examinations will be held at the discretion of the board at or near the time and place of national medical meetings. If a number of applications from any region of the country are received, an examination in conjunction with a national medical meeting in that section will be arranged so that the financial outlay of the applicant in meeting the examiners will be as small as possible.

The examinations are to be based on the broad principles of pathology with emphasis on diagnosis, interpretation and technique. The applicant may apply for certification in either pathological anatomy or clinical pathology or both.

The examinations in pathological anatomy consist of a written test, an oral examination on gross pathology, and a practical examination in microscopic pathology. The examination in clinical pathology consists of a written test and an oral and practical examination in the six phases of clinical pathology: bacteriology, hematology, clinical chemistry, parasitology, serology, and clinical microscopy.

DEFINITIONS

1. Pathological anatomy is that branch of pathology that deals with the morphological aspects of disease, recognition being given that that definition covers two phases of pathology: (*a*) the applied phase with special attention to the description and diagnosis of gross and microscopic specimens, (*b*) the academic phases of teaching and general morphological diagnosis.

2. Clinical pathology is that branch of pathology that deals with bacteriology, immunology, clinical chemistry, parasitology, hematology, endocrinology, clinical microscopy, and the application of the physical and biological sciences to the diagnosis, prognosis, and treatment of disease.

BOARD NOT AN EDUCATIONAL INSTITUTION

The board is in no sense an educational institution, and the certificates of the board are not to be considered degrees. Therefore, the certificate does not confer on any person legal qualifications, privileges, or license to practice medicine or the specialty of pathology. The board does not purport in any way to interfere with or limit the professional activities of any licensed physician. Its chief aim is to standardize the qualifications for the specialty of pathology and to issue certificates to those voluntarily complying with the requirements of the board.

CRITERIA FOR APPROVAL OF INSTITUTIONS FOR TRAINING IN PATHOLOGY

In Sections C-2-a, C-2-b, and C-2-c of the General Requirements, it is stated that candidates must have certain periods of supervised study and training. The American Board of Pathology, in cooperation with the Council on Medical Education and Hospitals of the American Medical Association, certifies hospitals in the United States as satisfactory for this supervised study and training. Lists of these hospitals are published in the Internship and Residency Number of The Journal of the American Medical Association each year. In addition, the American Board of Pathology recognizes certain hospitals outside the United States and certain laboratories not connected with hospitals in the United States. Inquiries concerning these should be directed to the secretary of the board.

The general criteria for approval of hospitals and laboratories are both qualitative and quantitative. On the score of quality, consideration is given to the qualifications of the director of laboratories and in the associates and assistants, the supervision of work of the person in training, the excellence of the educational program, and the exactness and completeness of the laboratory work performed. On the score of quantity, consideration is given to the volume and distribution of laboratory work, both in absolute numbers and in relation to the size of the hospital, to the diversity and completeness of tests performed, to the size and equipment of the laboratory, and to the number of professional and nonprofessional personnel in relation to the volume of work.

In general, the qualitative standards will determine whether or not a hospital or laboratory is approved, and the quantitative standards will determine whether the approval is for one, two, three, or four years of credit toward the requirements of the board.

In evaluation of applications the board takes into consideration the following criteria:

1. Director of laboratories or pathologist:
    - (*a*) It is required that the responsible head of the laboratory hold the certificate of the American Board of Pathology in the subject for which the hospital is approved, or be eligible for certification, and that he or she spend full time in the hospital. Full time is not interpreted in terms of hours, but rather that the director have no obligation outside the one approved hospital except in a university department of pathology in which he and the residents have an opportunity to participate in the educational program;
    - (*b*) In special instances, the equivalent of full time by two or more qualified persons will be accepted and one person need not spend the entire working day in the laboratory;
    - (*c*) In special instances, two or more hospitals will be approved as a unit with a single full-time director of laboratories if it is apparent that a satisfactory training program can be conducted;
    - (*d*) In hospitals with over 350 beds, it is expected that the professional staff, in addition to the pathologist, will include one or more persons with special training and qualifications in the subspecialties of clinical pathology.
2. Technicians:

    There are no absolute criteria, but it is expected that the number of technicians will be proportional to the volume of laboratory work and that, insofar as possible, the technicians will hold the certificate of the Registry of Medical Technologists of the American Society of Clinical Pathologists.
3. Floor space of laboratory:

    In general, it is believed that the size of the laboratory should be related to the size of the hospital and the volume of laboratory work. A minimal ratio is 4 sq. ft. of space in the laboratory, including morgue and autopsy room, for each bed in the hospital.
4. Equipment for the laboratory:

    The variety and completeness of laboratory tests performed depends on the size of the hospital. In all hospitals there should be facilities for the more common tests in clinical pathology, for study of surgical specimens, and for performance of autopsies. In larger hospitals, the variety of tests performed should be larger, and in hospitals with over 500 beds all recognized laboratory procedures should be available for study and treatment of the patients.

5. Autopsy percentage:

   No institution with a percentage of less than 15 will be approved, and those institutions with percentages between 15 and 40 will be given special scrutiny.

6. Examination of surgical specimens:

   All surgical specimens should be sent to the laboratory for gross examination, and microscopic examinations should be made unless there are general or special reasons not to do so.

7. Indices:

   There should be indices according to the names of the patients and the diagnoses of all surgical and autopsy material. *Indices of clinical pathology are left to the discretion of the hospital.*

8. Museum:

   There should be available fixed anatomic and pathological specimens for study by the staff in proportion to the size of the hospital. Property filed and indexed color photographs may in part be substituted for museum specimens.

9. Library:

   A reasonably complete library of modern books and recent unbound and bound journals should be available to the hospital, and the more commonly used books and journals should be on hand in the laboratory.

10. Education program:

    The work of the person in training should be supervised. Conferences, seminars, journal clubs, and demonstrations should be conducted as frequently as the volume of material and the size of the staff justifies. A clinicopathological conference must be held at least every two weeks.

11. Volume of laboratory work:

    (*a*) As indicated in the following categories, no hospitals with less than 75 autopsies, 1,000 surgical specimens, and 25,000 tests in clinical pathology annually will be approved (Category D), except as outlined in the following paragraphs. *It is the belief of the board that less material than this is inadequate for the training of a pathologist.*

    (*b*) In the field of clinical pathology, there should be a reasonable diversification of tests, and in each category there should be sufficient absolute volume to provide training and experience. There are no absolute criteria, but special scrutiny will be given to a hospital in which there is not a reasonable diversification and variety.

    (*c*) In the field of pathological anatomy, a deficiency in either autopsies or surgical specimens may be made up by an excess of the other, if the deficiency does not exceed 20% of the minimum required in the ratio of one autopsy to 75 surgical specimens. *Thus in a hospital approved for one year in pathological anatomy and clinical pathology, the minimums are 75 autopsies and 1,000 surgical specimens. If a hospital has 2,500 surgical specimens, it is acceptable if there are only 60 autopsies.*

If a hospital has met these minimal qualitative and quantitative standards, it will then, on the basis of the following quantitative standards, be approved for one, two, three, or four years of training in pathological anatomy, or clinical pathology, or both, or some special field as shown for the number of residents indicated.

CATEGORY A. In both pathological anatomy and clinical pathology for four years (as required of all candidates seeking certification in both fields who are examined after July 1, 1952).

Minimum: 150 autopsies, 1,750 surgical specimens, and 65,000 tests in clinical pathology for four residents. Additional resident for each 50 autopsies or 500 surgical specimens, or 20,000 tests in clinical pathology.

CATEGORY B. In both pathological anatomy and clinical pathology for three years. This meets all requirements of the board for supervised training until July 1, 1952. Candidates examined after that date who seek certification in both subjects must take an additional year of supervised training in clinical pathology or pathological anatomy in another hospital that is approved for the deficiency of training required.

Minimum: 125 autopsies, 1,500 surgical specimens, and 50,000 tests in clinical pathology for three residents. Additional resident for each 50 autopsies, 500 surgical specimens, or 20,000 tests in clinical pathology.

CATEGORY C. In both pathological anatomy and clinical pathology for two years. Candidates taking two years in these institutions must have an additional year (two years after July 1, 1952) in an institution in category A, B, or D.

Minimum: 100 autopsies, 1,250 surgical specimens, and 40,000 tests in clinical pathology for two residents. *Additional resident* for each 50 autopsies, or 500 surgical specimens, or 20,000 tests in clinical pathology.

CATEGORY D. In both pathological anatomy and clinical pathology for one year. Candidates taking training in these institutions must have an additional two years (three years after July 1, 1952) in institutions that are approved for the deficiency of training required.

Minimum: 75 autopsies, 1,000 surgical specimens, and 25,000 tests in clinical pathology for one resident. Additional resident for each 50 autopsies, or 500 surgical specimens, or 20,000 tests in clinical pathology.

CATEGORY E. In pathological anatomy only, for three or more years. Candidates taking all training in these institutions will not be eligible for certification in clinical pathology unless an additional year (two years after July 1, 1952) is taken in clinical pathology in institutions that are approved for the deficiency of training required.

Minimum: 175 autopsies and 1,500 surgical specimens for three residents. Additional resident for each 50 autopsies or 500 surgical specimens.

CATEGORY F. In pathological anatomy only, for two years. Candidates taking training in these institutions will not be eligible for certification in clinical pathology unless they take one additional year full time in clinical pathology (two years after July 1, 1952) in institutions that are approved for the deficiency of training required, and will be eligible in pathological anatomy only if another year is taken in another institution that is approved for one or more years in pathological anatomy.

Minimum: 125 autopsies and 1,250 surgical specimens for two residents. Additional resident for each 50 autopsies or 500 surgical specimens.

CATEGORY G. In pathological anatomy only, for one year. Candidates training in these institutions will not be eligible in both pathological anatomy and clinical pathology unless they take an additional year in pathological anatomy and an additional year (two years after July 1, 1952) in institutions that are approved for these periods of training. Candidates seeking certification in pathological anatomy only must study an additional two years in institutions that are approved for that period of training.

Minimum: 75 autopsies and 1,000 surgical specimens for one resident. Additional resident for each 50 autopsies or 500 surgical specimens.

CATEGORY H. For postmortem part of pathological anatomy for two years. Credit is never allowed for more than two years. Candidates taking training in these institutions may pursue further training as follows: 1. For pathological anatomy only. An additional year in an institution in Category A, B, C, E, F, or G with assignment to surgical pathology principally. 2. For pathological anatomy and clinical pathology. An additional year (two years after July 1, 1952) in an institution in Category A, B, C, L, M, or N with assignment to clinical pathology and one-half year assigned to surgical pathology principally, in an institution in Category A, B, C, or J.

Minimum: 125 autopsies for two residents. An additional resident for each 60 autopsies.

CATEGORY I. For postmortem part of pathological anatomy for one year. Candidates taking training in these institutions may pursue further training as follows: 1. For pathological anatomy only. An additional two years in an institution in Category A, B, C, E, F, or G with general assignments. 2. For pathological anatomy and clinical pathology. An additional year (two years after July 1, 1952) in an institution in Category A, B, C, L, M, or N with assignment to clinical pathology and one year to an institution in Category A, B, C, E, F, or G.

Minimum: 75 autopsies for one resident.

Category J. Surgical pathology part of pathological anatomy for one year. Credit is never allowed for more than one year and the director of the laboratory must hold the certificate of the American Board of Pathology in pathological anatomy or be eligible for certification. Candidates training in these institutions may pursue further training as follows: 1. For pathological anatomy only. An additional two years in an institution in Category H or in an institution of Category A, B, or C with assignment to postmortem pathology only. 2. For pathological anatomy and clinical pathology. An additional year (two years after July 1, 1952) in an institution in Category A, B, C, L, M, or N with assignment to clinical pathology full time, and an additional year to an institution in Category A, B, D, E, F, G, or H with assignment to postmortem pathology full time.

Minimum: 2,000 surgical specimens for one resident. An additional resident for each 1,000 surgical specimens.

Category K. Special pathology as part of pathological anatomy. Credit for not to exceed one-fourth the time credit (one year if seeking certification in pathological anatomy only, six months if seeking both pathological anatomy and clinical pathology) of candidates applying in pathological anatomy may be taken in special laboratories with limited activities such as neuropathology, orthopedic pathology, ophthalmic pathology, etc. The candidate who receives credit in this category may, on request, have the field of special pathology designated on the certificate of the board.

Category L. Clinical pathology for three or more years. Candidates taking three years of training in these institutions will not be eligible for pathological anatomy unless they take an additional two years in institutions approved for pathological anatomy.

Minimum: 100,000 tests in clinical pathology for three residents. Additional resident for each 50,000 tests.

Category M. Clinical pathology for two years. Candidates taking two years' training in these institutions must take the same additional training as in Category L to be eligible for pathological anatomy also. To be eligible for clinical pathology only, an additional year of clinical pathology must be taken in an approved institution.

Minimum: 75,000 tests in clinical pathology for two residents. An additional resident for each 50,000 tests.

Category N. Clinical pathology for one year. Candidates taking training in those institutions must take an additional two years in an institution in Category A, B, C, L, or M assigned to clinical pathology for eligibility in clinical pathology only. To be eligible in pathological anatomy and clinical pathology, an additional two years in approved institutions is required.

Minimum: 50,000 tests in clinical pathology for one resident.

Category O. Special clinical pathology as part of clinical pathology. Candidates applying for clinical pathology only may receive credit for not in excess of one-quarter of the training period (one year if seeking certification in clinical pathology only, six months if seeking both pathological anatomy and clinical pathology) for work in a special field of clinical pathology, such as bacteriology, serology, etc. Under these circumstances, on request, the special field will be designated on the certificate of the board.

Category P. Research: residence in certain institutions in which full time is devoted to research with a direct application to the practice of pathological anatomy or clinical pathology may be accepted for credit not to exceed one-third the time requirement (20 months if no clinical internship, 16 months if a clinical internship was taken). The board encourages research and believes that all candidates should carry on investigation during their training in all institutions. Therefore, this category is only for those wishing to do full-time research.

AMERICAN BOARD OF PEDIATRICS

Lee F. Hill, President, Des Moines, Iowa.
J. A. Johnston, Vice-President, Detroit.
Ralph V. Platou, Secretary-Treasurer, New Orleans.
James M. Baty, Boston.
James G. Hughes, Memphis, Tenn.
Robert B. Lawson, Miami, Fla.
Waldo E. Nelson, Philadelphia.
Henry G. Poncher, Valparaiso, Ind.*
A. Ashley Weech, Cincinnati.
John McK. Mitchell, Executive Secretary, 6 Cushman Rd., Rosemont, Pa.

REQUIREMENTS FOR CERTIFICATION [1]

All candidates for examination for certification must meet the following requirements:

1. Graduation from an approved medical school.

2. Hold a license to practice in the United States prior to issuance of a certificate except in those situations in which a license to practice is not required.

3. One year of rotating, pediatric, or other internship in an approved hospital.

4. Two years of specialized residency-type training in an approved pediatric center.

At least one year of the two years of required residency training must be a full-time medical pediatric inpatient residency or internship in an approved institution. The second year of required residency training may be met in the ways listed below, although the board recommends that whenever possible candidates complete the two years as regular residents.

(*a*) It is the fundamental concept of the American Board of Pediatrics that a residency training program should provide for properly organized progressive responsibility for the care of sick children. The board believes further that this purpose can be accomplished only through continuity of clinical experience under the supervision of staff physicians who are themselves responsible for the care of children on the service. The substitution of a formal course in a graduate or postgraduate school which does not carry the essential ingredient of responsibility for patient care is, in the opinion of the board, inconsistent with this principle. Accordingly, the board in the future will accept such courses as part of an approved residency program in pediatrics only in exceptional cases authorized by the board in advance of the same. The above provision will be considered to become effective on and after July 1, 1956.

In "exceptional cases," there are a small number of applicants for whom graduate school courses may be substituted for equivalent periods of residency training with benefit. These include certain physicians whose basic training may for one reason or another have been deficient or may have been gained such a long time in advance of completion of specialty training that graduate school training would be very helpful. In such cases, by prior arrangement, credit may be allowed for the same to a maximum of nine months.

(*b*) A maximum of three months' credit each is allowed for full-time residency type training in allied pediatric subjects such as pediatric allergy, pediatric psychiatry, pediatric pathology, pediatric radiology, newborn service, etc.

(*c*) A maximum of six months' credit is allowed for residency training in an approved contagious disease hospital.

5. A subsequent term of two years of specialized study or practice or a combination of the two. Credit for one year toward this requirement is allowed for medical military service regardless of the assignment. Credit in excess of one year may be

---

* Deceased.

[1] To avoid misunderstanding, the board urges any candidate whose training is not clearly covered in these regulations to communicate with the office of the executive secretary. Whenever possible, this should be done before entering upon the appointment in question.

granted if the medical officer is engaged in full-time pediatrics, or may be prorated if a considerable proportion of time is spent in pediatrics. It must be noted, however, that the maximum credit that any candidate may receive toward the practice requirement for work done prior to the completion of residency training is one year.

Attention is invited to the fact that the primary duty of the resident must be the care of patients under supervision, if full credit in satisfaction of the residency training requirement is expected. Research residencies which involve little or no clinical training are creditable for only three months. Research residencies which include significant clinical training may be prorated to a total of six months for a year of service. Teaching fellowships may not be offered in lieu of residency appointments.

Both research residencies and teaching fellowships are, of course, entirely acceptable in satisfaction of the practice or further study requirement. Portions of a research residency not applicable for residency training credit may be carried over for practice credit.

Preceptorships are not accepted for credit toward the residency requirement, but are accepted toward the practice requirement.

The board defines service in a pediatric center as full time devoted to rounded experience in an approved hospital which includes responsibility for care of patients on ward and outpatient services, experience with newborn, including prematures, and both therapeutic and preventive pediatrics. It is expected that the service will include adequate graduate training in the basic medical sciences, as well as in the clinical, laboratory, and public health aspects of the specialty.

GRADUATES OF MEDICAL SCHOOLS IN CANADA

Graduates of approved medical schools in Canada and those who have received their internship and residency training in pediatrics in hospitals approved by the Royal College of Physicians and Surgeons of Canada will be eligible for examination for certification under the same regulations as those trained in the United States.

GRADUATES OF FOREIGN MEDICAL SCHOOLS

Citizens of the United States.—Citizens of the United States of America who are graduates of medical schools other than those in the United States and Canada will be processed for eligibility for examination for certification if they can meet all the following requirements:

1. They are graduates of a medical school recommended by the Council on Medical Education and Hospitals of the American Medical Association.
2. They hold a license to practice in the United States.
3. They can meet the internship and residency training requirements of the board as detailed above with the following provisions:
   (*a*) Internship and residency training must be served in hospitals approved by the board in the United States.
   (*b*) A maximum of the internship and one year of residency training may be allowed for such experience obtained in a small list of foreign hospitals recognized by the board. The other year of residency training must be served in a straight inpatient medical pediatric residency appointment in an approved hospital in the United States.

Citizens of the United States of America who are graduates of medical schools other than those in the United States and Canada, which are not recommended by the Council on Medical Education and Hospitals of the American Medical Association, may be accepted for examination for certification after they have passed successfully parts 1 and 2 of the examinations of the National Board of Medical Examiners, Inc., provided they meet the other requirements of the board as provided in the regulations governing such candidates. It should be noted that this regulation is permissive, not mandatory. Each application will be evaluated individually.

Citizens of Other Countries.—Properly qualified candidates who are permanent residents in and citizens of other countries and are licensed to practice there and who have fulfilled the residency training requirements listed above in the United States or Canada may apply for examination for certification by the American Board of Pediatrics.

Such foreign candidates who are returning to their own country at the end of their training period may be examined withou completion of two full years in the practice of pediatrics. Th residency training requirements must be completed in full i advance of admission to any part of the examinations.

A special certificate, appropriately identified to distinguish from the regular certificate of this board, may be issued to suc candidates who have passed successfully the examinations this board after they have completed such a period of practic or further study in their own country which, when added similar experience in the United States or Canada, make a tota of two years of the practice of pediatrics.

APPLICATION

Application must be made on special blanks, which will be furnished by the executive secretary after a preliminary survey of the applicant's training. Applications may be submitted one year in advance of eligibility date; they will not be accepted earlier. The number of candidates admitted to a given written examination will be determined by the number who can be examined orally during that year, plus a reasonable number of alternates.

LETTERS OF RECOMMENDATION

Letters from two competent pediatricians recommending each applicant must be sent to the executive secretary of the board. These letters should not accompany the application but should be sent directly to the executive secretary.

FEES

The application fee is $100.

The full fee must be remitted with the application. Refund will be made only if the applicant is refused examination for reason other than failure in the same.

No additional fee is required for second and third written examinations. The fee for second and third oral examinations is $50 each.

Members of the board receive no financial recompense of any kind beyond their travel expenses to examinations and board meetings.

FAILURE IN EXAMINATIONS

As indicated above, a written examination must be passed before a candidate is eligible for oral examination. Written reexaminations may be taken one and two years later. After a third failure, the situation will be reviewed by the board and a decision concerning subsequent procedure will be made.

Applicants who fail an oral examination become eligible for a second examination after a year has elapsed. After a second failure another examination will be permitted in one year. Before becoming eligible for a fourth examination a candidate must serve one year in a full-time medical inpatient residency in an approved institution. He must then reapply as a new candidate and pay a new fee.

POSTPONEMENT OF EXAMINATION

After acceptance of his application a candidate is expected to take the next written examination offered. If desired, he may postpone this examination for one more year. Any further postponement must be for due cause acceptable to the board.

After having passed the written examination, a candidate must appear for oral examination within two years, unless excused for due cause by the board.

After failure in either part 1 or part 2, a candidate must appear for reexamination within two years unless excused for due cause by the board.

Failure to appear for examination within the period indicated above, unless excused by the board, will result in loss of eligibility to appear for examination. In order to be reinstated, a candidate must then submit a new application and a new fee.

PURPOSE OF EXAMINATIONS

The purpose of these examinations is to determine the applicant's competency to practice pediatrics of high quality. Emphasis is therefore placed on practical aspects, but since good practice is founded on sound scientific data, the candidate must be prepared to demonstrate that he has a working knowledge of these basic data.

Clinical and abstract aspects of growth and development are fundamental parts of pediatric training, and about one-fourth of the oral examination is devoted to this phase of the subject. Diagnosis and treatment of disease fill another quarter, and the remainder of the examination is devoted to study and discussion of "cases."

Candidates who are admitted to the oral examination (part 2) will not be informed of their grade on the written portion. Their relative standing in part 1 will, however, be utilized in the final decision with regard to passing.

Candidates who fail after taking part 2 will not be required to retake part 1 but may be advised to do so in order that they may have an opportunity to improve a low score.

CERTIFICATION IN SUBSPECIALTY OF ALLERGY BY THE AMERICAN BOARD OF PEDIATRICS, INC.

Members—Subspecialty Board of Pediatric Allergy

William P. Buffum, Chairman, Providence, R. I.
William C. Deamer, San Francisco.
Jerome Glaser, Rochester, N. Y.
George B. Logan, Rochester, Minn.
James Overall, Nashville, Tenn.
Bret Ratner, New York.

The American Board of Pediatrics, Inc., has established certification in allergy as a subspecialty of pediatrics.

All candidates must pass the written and oral examinations in pediatrics before submitting an application for examination in allergy.

Each allergy application is individually considered and must be accepted by the subspecialty board.

INFORMATION CONCERNING EXAMINATIONS

Allergy examinations consist of written and oral portions. The written examination will be given once a year under a local monitor and must be passed before admission to the oral examination will be authorized. Oral examinations will be held at times and places designated by the chairman of the subspecialty board. Ample notice will be sent to candidates by the executive secretary.

FAILURE IN EXAMINATIONS

As indicated above, a written examination must be passed before a candidate is eligible for oral examination. Reexaminations may be taken one and two years later. After a third failure, the situation will be reviewed by the board and a decision concerning subsequent procedure will be made.

Applicants who fail an oral examination become eligible for a second examination after a year has elapsed. After a second failure another examination will be permitted in one year. Before becoming eligible for a fourth examination a candidate must serve one year full time in a satisfactory allergy clinic and its hospital including training in both allergy and pediatrics.

FEES

The application fee for certification in allergy will be $100 effective July 1, 1952.

The full fee must be remitted with the application. Refund will be made only if the applicant is refused examination for reason other than failure in the same.

No additional fee is required for second and third written examinations. The fee for second and third oral examinations is $50 each.

Members of the board receive no financial recompense of any kind beyond their travel expenses to examinations and board meetings.

Application forms will be forwarded on request to the office of the executive secretary and should be returned to that office when completed. All correspondence should be addressed to him.

REQUIREMENTS

1. Certification in pediatrics.
2. Two years full time of approved allergy residency or fellowship training in an approved clinic and its hospital, or
3. One year full time of approved allergy residency or fellowship training and two years, part time, 200 hours a year in an approved clinic and its activities, or
4. Five years, part time, 200 hours a year in an approved allergy clinic and its activities.
5. Preceptorship alone is not acceptable, but a resident or fellow doing full-time work in allergy may spend part of his time working with private patients in the hospital or in the office of an allergist qualified to give this training.

Until clinics are officially approved the candidate should assure himself that the clinic is satisfactory for training by writing to the executive secretary of the Board of Pediatrics. In general such clinics will be in hospitals that have been accepted by the Council on Medical Education and Hospitals of the American Medical Association and by the American Board of Pediatrics for training in pediatrics, or have been approved for training in allergy by the Board of Pediatric Allergy or of Internal Medicine.

Under all methods of study there must be presented evidence of serious work in research or clinical investigation.

The candidates must be prepared for a searching examination in the theory and practice of allergy. This will include the theory of the underlying mechanisms, animal experimentation, the clinical manifestations in the so-called allergic diseases, especially as they appear in infants and children, and also the allergic factors that may be present in other diseases. They must be prepared to discuss the important diagnostic procedures and methods of treatment and, in controversial matters, they must be familiar with the arguments on both sides of the question.

CERTIFICATE

When accepted the diplomate will receive from the American Board of Pediatrics a certificate in allergy and will be listed as a specialist in allergy.

Prospective applicants for certification in the subspecialty of allergy may apply to the executive secretary of the American Board of Pediatrics.

AMERICAN BOARD OF PHYSICAL MEDICINE AND REHABILITATION

Robert L. Bennett, Chairman, Warm Springs, Ga.
William H. Schmidt, Vice-Chairman, Philadelphia.
William Bierman, New York.
Donald A. Covalt, New York.
Kristian G. Hansson, New York.
O. Leonard Huddleston, Santa Monica, Calif.
A. B. C. Knudson, Washington, D. C.
Frederic J. Kottke, Minneapolis.
Arthur L. Watkins, Boston.
Walter J. Zeiter, Cleveland.
Earl C. Elkins, Secretary-Treasurer, 200 First, S.W., Rochester, Minn.

QUALIFICATIONS FOR ELIGIBILITY TO EXAMINATION FOR CERTIFICATON

Each applicant for admission to the examination shall be required to present evidence that he has met the following standards:

A. *General:*

1. Satisfactory moral and ethical standing in the profession.

2. A legal license to practice medicine in one or more of the states of the United States of America or its territories, or the District of Columbia, or one or more of the provinces of Canada.

B. *Professional:*

1. Graduation from a medical school approved by the Council on Medical Education and Hospitals of the American Medical Association or graduation from a foreign medical school which, in the opinion of the board, offers medical education equivalent to such an approved school.
2. Completion of an internship in a hospital approved by the same Council.

C. *Special Training:*

1. A period of study after the internship of not less than three years in clinics, dispensaries, hospitals, or laboratories recognized by the same Council and by the American Board of Physical Medicine and Rehabilitation as competent to provide a satisfactory training in physical medicine and rehabilitation. Each year of training in such an approved program counts as two units against a total of eight units, necessary for eligibility to both parts 1 and 2 of the examination (see below). A total of only six credits may be earned in this manner.
2. This period of specialized preparation shall include: (1) graduate training in anatomy (including kinesiology and functional anatomy), physics (including radiation physics, electronics, and medical instrumentation), physiology, pathology, and other basic sciences that are necessary to the proper understanding of physical medicine and rehabilitation; (2) an active experience of not less than two years in hospitals, clinics, dispensaries, and diagnostic laboratories recognized by the Council on Medical Education and Hospitals and the American Board of Physical Medicine and Rehabilitation.
3. An additional period of not less than two years of practice in physical medicine and rehabilitation. One unit of credit is granted for each year of practice in physical medicine and rehabilitation.
4. Experience comparable to specialized training. Training in approved residency programs in closely allied medical-surgical fields may be acceptable in whole or in part, but maximum credit is limited and based on individual interpretation by the board. In selected cases, at the discretion of the board, two years of specialization in physical medicine and rehabilitation may be accepted as equivalent to one year of formal training.

METHOD OF EXAMINATION

The examination for certification by the American Board of Physical Medicine and Rehabilitation is given in two parts. Part 1 is written, part 2, oral. Part 1 alone may be taken after the completion of six units of credit. Upon the completion of part 1, part 2 may be taken after an additional two units of credit are obtained. Parts 1 and 2 combined may be taken only after a total of eight units of credit have been obtained.

The written and oral examination will cover certain aspects of the basic sciences as well as clinical physical medicine and rehabilitation.

A. The basic sciences as related to physical medicine and rehabilitation will include:

1. Anatomy (including kinesiology and functional anatomy).
2. Physics (including radiation physics, electronics, and instrumentation).
3. Physiology (including physiology of movement and physiological effect of the various physical agents used in physical medicine and rehabilitation).
4. Pathology.
5. Other fundamental sciences. The applicant will be examined concerning his knowledge of such subjects as biochemistry and bacteriology as related to physical medicine and rehabilitation.

B. The clinical aspects of physical medicine and rehabilitation will include:

1. Those diseases and conditions that come within the field of physical medicine and rehabilitation. These include arthritis and the various rheumatic diseases, neuromuscular diseases such as poliomyelitis, cerebral palsy, and paraplegia and musculoskeletal diseases, including the large group of traumatic and orthopedic conditions.
2. The clinical usage of such physical agents as heat, water, electricity, ultraviolet radiation, massage and exercise, etc.
3. A knowledge of the role of associated personnel within the field of physical medicine and rehabilitation such as the physical therapist, occupational therapist, clinical psychologist, social service worker, and vocational guidance counselor, and the ability to coordinate the services of such personnel.
4. An understanding of the basic principles of physical medicine and rehabilitation, and the ability to prescribe specific treatment to be executed by technical and ancillary personnel.

APPLICATION

The application form shall contain a record of the candidate's premedical and medical training as well as of internships, graduate study, hospital or dispensary staff appointments, teaching positions, length of time practice has been limited to physical medicine and rehabilitation, medical papers published, and the names of three well-known physicians to whom the board may write for professional and character references. Three letters of reference must be submitted with the application.

The application shall also be accompanied by one recent signed photograph of the candidate mounted on the application, and by the fee of $100, which fee will cover the evaluation and both the written and oral examinations. (In case of rejection of application, this fee will be refunded with the exception of $15, which will be considered an evaluation fee.)

CERTIFICATES

The certificate issued by the American Board of Physical Medicine and Rehabilitation shall be in such form as to comply with the articles of incorporation and bylaws and shall be signed by the chairman and the secretary-treasurer of the board and shall bear the official seal of the board.

Certificates of the board shall be issued to the effect that the applicant has been found qualified to practice physical medicine and rehabilitation.

AMERICAN BOARD OF PLASTIC SURGERY

Gustave Aufricht, Chairman, New York.
Wm. Milton Adams, Vice-Chairman, Memphis, Tenn.
Truman G. Blocker Jr., Galveston, Texas.
Bradford Cannon, Boston.
Albert D. Davis, San Francisco.
S. Milton Dupertuis, Pittsburgh.
Frederick A. Figi, Rochester, Minn.
Paul W. Greeley, Chicago.
Edward A. Kitlowski, Baltimore.
Gerald B. O'Connor, San Francisco.
A. Neal Owens, New Orleans.
Kenneth L. Pickrell, Durham, N. C.
Lyndon A. Peer, Newark, N. J.
Clarence R. Straatsma, New York.
Frank McDowell, Secretary-Treasurer, St. Louis
Estelle E. Hillerich, Corresponding Secretary, 4647 Pershing Ave., St. Louis 8.

GENERAL REQUIREMENTS FOR QUALIFICATION

The following requirements are in agreement with those promulgated by the Advisory Board for Medical Specialties and by the Council on Medical Education and Hospitals of the American Medical Association.

1. Moral and ethical standing in the profession satisfactory to the board.

The board, believing that the practice of "fee splitting" is pernicious, leading as it does to traffic in human life, will reserve the right to inquire particularly into any candidate's practice in regard to this question.

2. Those whose activities are limited to the practice of plastic surgery.

3. This board will accept as applicants for examination only those who are full citizens of the United States or Canada. Notarized statements, not original citizenship papers, attesting to the fact of full citizenship in the United States or Canada must be furnished by foreign-born applicants when the application is filed. Such candidates must have at least two years of practice in plastic surgery in North America after completing the training required by the board.

PROFESSIONAL REQUIREMENTS FOR QUALIFICATION

The board considers the requirements outlined below to be minimal in attaining its purposes and encourages candidates to take advantage of broadening experience in other fields. Candidates must fulfill the requirements that are in force at the time of their examination and/or certification.

1. Graduation from a medical school of the United States or Canada recognized by the Council on Medical Education and Hospitals of the American Medical Association, or graduation from a foreign school considered acceptable by the board.

2. Completion of an internship of not less than one year in a hospital approved by the same council.

3. Two years of postgraduate work in general surgery, beyond the intern year, as a resident or an assistant resident in a hospital approved by the same council.

4. Training in general plastic surgery, including maxillofacial surgery, for an additional period of not less than two years in a residency approved by the same council, or in a preceptorship approved by the board. In fulfilling this requirement, there is a limit of one year's credit given for all work done in all governmental plastic surgery residencies (Army, Navy, VA hospitals, etc.) regardless of the time put in by trainees in such residencies. It is required that all such trainees take one additional year of approved training in plastic surgery in a civilian residency or preceptorship.

5. During these years of training following the internship year, a candidate must hold positions of increasing responsibility for the care and management of patients with surgical conditions. When a candidate receives his training in more than one institution, it is equally imperative that he hold positions of increasing responsibility. He must have sufficient operative experience to acquire surgical skill and judgment through the performance of surgical operations with a high degree of responsibility, but under circumstances providing adequate opportunity for consultation and advice.

6. An additional period of not less than two years of practice in plastic surgery. If a candidate elects to spend one or two additional years in approved training in plastic surgery, one year of such training will be credited toward the required two years of private practice if it can be demonstrated that the candidate held a position of increasing responsibility. It is imperative that one year be in actual private practice in such instances.

The above training in plastic surgery may be taken as a resident in an approved hospital or under an approved preceptorship offering equivalent training (a list of currently approved preceptorships is available from the board office). By the latter statement it is meant that one may secure the necessary and specified training as an assistant to an accredited plastic surgeon provided suitable facilities for the education of the candidate are offered.

The period of special training should emphasize the relation of the basic sciences—anatomy, pathology, physiology, biochemistry, bacteriology—to the application of surgical principles which are fundamental in all branches of surgery, and especially to plastic surgery. In addition, the candidate must understand and be trained in the following subjects: the care of emergencies, shock, hemorrhage, blood replacement, electrolyte and fluid balance, choice of anesthetics, chemotherapy, acidosis and alkalosis, narcotics and hypnotics, wound healing, etc.

The board reserves the privilege of requesting lists of operations done solely by the candidate for one or more years, or of requesting special and extra examinations, written or oral and practical, and of requesting any specific data concerning the candidate that may be deemed advisable before making final decision for certification.

Eligibility rulings or an evaluation of a candidate's qualifications or training cannot be made by the secretary or by any one member of the board. Official evaluations of qualifications are made only by the committee on credentials and requirements, or by the entire board where necessary, after a review of the candidate's formal application for such rulings. The applicant must allow at least two months for such requests to make the rounds of the committee.

TRAINING FACILITIES

Residencies.—The American Board of Plastic Surgery, in cooperation with the Council on Medical Education and Hospitals of the A. M. A. and the American College of Surgeons, evaluates training facilities in institutions providing acceptable residencies in plastic surgery. The board does not assume the responsibility for independent inspection and approval of residencies. It will inspect and make recommendations for or against approval of a residency in plastic surgery only after the director of the residency has applied to the Council on Medical Education and Hospitals of the American Medical Association for approval of the residency, and after the Council has notified the board to that effect. Therefore any diplomate of the board wishing approval of a residency under his supervision should apply to the Council for such approval. The board will make its own inspection, preferably at the same time as the A. M. A. Council inspection, and will report its findings to the Council. Upon completion of consideration by the Council and the board, the hospital will be notified by the Council of the joint action that has been taken, and the hospital and the secretary of the board will be notified simultaneously by the Council to avoid any misunderstanding as to the status of the program.

Preceptorships.—In certain instances the board will accept, in lieu of the required two years' training in an approved residency, training in a preceptorship under a fully qualified plastic surgeon when such preceptorship is properly organized and supervised to give the trainee adequate experience and training in plastic surgery of a well-rounded nature. Certain established preceptorships are given full approval. New preceptorship programs will be given tentative approval in advance on presentation to the board by the preceptor of a well-rounded plan of training. In such instances, the trainee will be required to keep a detailed record of his experience, presenting this report to the board at intervals of six months, on a report form supplied by the board on request. If the preceptorship program of training is found adequate in scope, it will be transferred to the fully approved list. In preceptorship programs of training it would be well for the preceptor to report annually to the board the name and qualifications of any preceptee under his supervision and the work done by the preceptee. (Application forms for requesting tentative approval of preceptorship programs of training are available from the board office.) Neither the board nor its individual members can be responsible for the placing of applicants for training. The board considers those residencies approved by the Council on Medical Education and Hospitals of the A. M. A. as acceptable facilities for training in plastic surgery.

It should be kept in mind by all that the primary interest of the board is to encourage well-rounded training in plastic surgery with the aim of producing plastic surgeons capable of doing good work in the wide variety of cases which may come under their care. The standards set up by the board, both for preliminary general surgery and for specialized plastic surgery training, are established in an effort to further this aim. The quality of the training received should be reflected in the candidate's ability to achieve good results in his practice, and the examinations of the board are an attempt to judge the ability of the candidate in the specialty of plastic surgery.

A residency in plastic surgery is one in which a hospital appointment for training in plastic surgery is given the trainee. In a preceptorship in plastic surgery no such appointment is given.

While the board permits flexibility in training, approved residencies and preceptorships should be under fully qualified plastic surgeons. Those trained in preceptorships will be judged by the candidate's ability to make the most of his training and to show adequate ability in all phases of the subject.

There must be teaching in either a residency or a precpetorship—instruction in the basic sciences and in the basic principles of plastic surgery—if not in actual courses, then by conferences, ward rounds, lectures by men on the service or other services, or by visiting doctors.

A resident or assistant resident in plastic surgery should have a full-time appointment from an A. M. A. Council-approved hospital or hospitals. A preceptee does not have such an appointment. A residency should preferably be in connection with a teaching hospital having medical school affiliations or be under the Dean's Committee of Veterans Administration hospitals. An acceptable residency is one that is approved by the Council on Medical Education and Hospitals of the American Medical Association.

Before training in plastic surgery is begun, the plastic surgeon in charge of the residency or preceptorship should ascertain that the trainee's preliminary training in general surgery meets the requirements of the board, that is, two years of residency training in general surgery after the internship year.

The training in plastic and maxillofacial surgery (at least two years) whether in a residency or a preceptorship, should cover a wide field of plastic surgery, both as to type and anatomic distribution. It should include experience in the treatment of congenital and acquired defects and deformities of the face, neck, body, and extremities, for both functional and esthetic reasons. There should be available sufficient material of a diversified nature so that the trainee will be able to pass the examinations of the board after the period of training and the two additional years of private practice. If the available material on one service is inadequate, the deficiency should be made up by affiliation with another plastic surgeon on another service so that a broad experience will be obtained in plastic surgery. The trainee should be provided an opportunity to operate under the direct supervision of the plastic surgeon in charge, and with increasing ability, should be given an opportunity to operate independently on suitable cases under more remote supervision.

RESIDENCY INFORMATION SERVICE

The Council on Medical Education and Hospitals of the American Medical Association maintains a "Residency Information Service," published quarterly, giving lists of available residency appointments in approved services in the specialties. Anyone having a residency opening in plastic surgery training should submit the information to the Council. This bulletin, showing available openings in residency appointments in plastic surgery, and other specialties, may be had from the Council on request.

MILITARY CREDIT

Credit for military service is given on an individual basis, each case being considered on its own merits and the amount of credit allowed is determined by the board when the information is submitted with the application.

MEDICAL OFFICER'S PROFESSIONAL TRAINING RECORD

The Medical Officer's Professional Training Record (DD Form 408) is a record maintained by individual Medical Corps officers for presentation to the various authorized accrediting boards toward certification. This record is presented by the officer to the boards for evaluation of the miliary experience acquired by Medical Corps officers while serving in the Army Medical Service. This form has been prepared by the Surgeon's General of the armed services with the assistance of the Council on Medical Education and Hospitals of the American Medical Association and is distributed by the offices of the Surgeons General to their personnel. It is highly important that prospective applicants obtain a copy of this form and that it be submitted with their credentials for evaluation by the board.

CASE REPORTS

Upon approval by the board of a candidate's application for certification, each candidate is required to submit to the board 35 or more case reports illustrative of his independent work in the field of general plastic surgery.

Candidates are admitted to examination only after submitting case reports that meet the required standards of the board and that have been approved by the committee on credentials and requirements.

Case reports must be submitted within one year from the time of such request; otherwise a new application must be filed. The case reports shall conform to conditions which the board may from time to time specify.

Case reports must be received in the office of the board by Jan. 1 for those who desire to be considered for the spring (May-June) examinations of the board and by June 1 for the fall (October-November) examinations. There will be no exceptions to these two deadlines.

The 35 case reports must be of a diversified nature and must be submitted to the office of the board together with before and after photographs. They should be of the following distribution:

1. Cleft lip: 1 to 3 cases
2. Cleft palate: 1 to 3 cases
3. Traumatic defects requiring reconstructive surgery:
    - (*a*) Face and neck: 2 to 4 cases
    - (*b*) Body: 1 to 4 cases
    - (*c*) Extremities: 1 to 6 cases
4. Acute burns: 2 to 4 cases
5. Fracture of facial bones, excepting nasal fractures: 1 to 3 cases
6. Esthetic operations of sufficient variety: 6 to 12 cases
7. Plastic surgery of the hand: 2 to 4 cases
8. Malignancies, or conditions prone to malignancies (eradication and repair):
    - (*a*) Face: 2 to 4 cases
    - (*b*) Body: 1 to 3 cases
    - (*c*) Extremities: 2 to 4 cases
9. Congenital anomalies: 1 to 6 cases
    - (*a*) Examples:
        - (1) Syndactylism
        - (2) Congential absence (partial or total) of external ear
        - (3) Hypospadias
        - (4) Bands (constricting)
        - (5) Thyroglossal duct cyst
        - (6) Extensive nevi, etc.

To be accepted, case reports must be assembled according to the following instructions. The group must include a variety of material from the entire body rather than a number of cases of one type and should carry the candidate's personal deductions, conclusions, and comments and should be sufficiently detailed to show if the conclusions drawn indicate a grasp of the subject and if the results justify the procedure.

Each case report should be individually assembled, typed on letter-size paper (8½ x 11 in.), with the candidate's name and the number of the case on each page. Each report should have a cover-sheet with the candidate's name, the number of the case, hospital number, diagnosis, and a brief summary of the case. The pages of each case should be stapled together securely and placed in an ordinary manila letter-file folder (nothing heavier). Do not use paper fasteners of any kind; merely staple the pages together with one staple in the upper left-hand corner. Photographs of conditions, before and after operation, and drawings of operative technique illustrative of each case should be included and attached to each case. Mount the photographs on a sheet of letter-size paper, or manila file-folder paper (nothing heavier), with the name of the candidate and the number of the case indicated. The photographs should be uniform in size, not less than 3 x 4 in. (kodachrome transparencies not acceptable; enlargements accepted), made by a sharp focus lens from untouched negatives with identical lighting conditions, exposure, and developing, not reversed, to show conditions before and after operations with clear detail. Each case report should be placed in a manila letter-file folder with the number of the case and the candidate's name on the outside (upper, right-hand corner) of folder.

Cases should be chosen from the private practice of the candidate or from the hospital or clinic service. The initials, color, age, and occupation of each patient should be stated, as should the name of the hospital where treated and dates of admission, operation, and discharge. The important details of family history, if relevant, and of the previous history should be given. The condition for which the patient consulted candidate should be stated clearly and concisely, indicating previous treatment, if any, and the mental, social, or economic factors involved. The physical examination of the patient with special reference to the existing deformities should be carefully described. All laboratory and other special examinations, such as roentgenograms, which were made should be reported, with a statement of what was determined by them. The indications for operation and for the type of operation employed should be given, and the preliminary treatment and the type of anesthesia used should be stated. A full description of the operative technique with methods of hemostasis, suture, and drainage, if any, and the name of the assistant should be given. The early and late postoperative course and results should be described.

If the case reports and lists of operations are approved, the candidate will receive subsequent information regarding taking the examinations. The board at its discretion may request certification of case reports by the hospital where the operations were performed. The following form should accompany the case reports: "I hereby certify that the planning and essential surgical procedures described herein were carried out by me as an independent operator."

Every candidate's final acceptability for examination is based not only on the evaluation of his training qualifications, but on his professional ability as a plastic surgeon, his ethical standing in the community, and the strict limitation of his work to plastic surgery.

A candidate should remember that these case reports are documentary evidence of his ability and that the material in them and the manner of presentation are important evidences of his ability.

EXAMINATIONS

In instances where a candidate submits case reports that do not meet the standards of the board, he will be required to submit additional case reports or an entirely new set of 35 within a period of one year. If this second series of case reports again do not meet the standards of the board, the candidate may be required to take additional training (of length and type specified by the board) before he will be allowed to submit any further case reports.

After a candidate has been notified that he has fulfilled the preliminary requirements and that his case reports have been approved, he will be required to take the qualifying examination within a period of three years.

After approval of the case reports, and prior to the examination, the candidate will be visited at his place of practice by a member or members of the board to observe him operate and to examine a number of his preoperative and postoperative cases.

The qualifying examinations are given twice yearly, in the spring and fall. The spring examination is given immediately preceding, during, or following the annual meeting of the American Association of Plastic Surgeons (usually in May), and the fall examination is given immediately preceding, during, or following the annual meeting of the American Society of Plastic and Reconstructive Surgery (usually in September or October). Candidates are required to go to the designated center for the qualifying examination, which will last three days. These centers will be the city in which the meetings of these two organizations are held if the proper clinic and hospital facilities are available, otherwise in some nearby city where such material is available. Arrangements for all examinations are made by the examination committee.

A written examination will consume all of the first day and half of the second day. An oral and practical examination will consume the afternoon of the second day and all of the third day. The subjects of the written examination are (1) theory and practice of plastic surgery, (2) applied anatomy, applied physiology, (3) pathology, bacteriology, clinical laboratory methods (pharmacology), (4) reaction of tissue to injury, surgical accidents, anesthesia. A general oral examination pertaining to plastic surgery will be given. In the practical part of the examination, the examiners will present a group of patients for examination by the candidates, and the candidates will be quizzed on methods of procedure—diagnosis, treatment, technique, and so on. Slides of preoperative conditions will be shown on a screen and the candidate asked to make a quick diagnosis of the items and to tabulate in the order of their importance the methods of treatment. Microscopic slides of the average pathological tissue falling within the province of the plastic surgeon will be given the candidates, and they will be asked to write a description and diagnosis.

GRADES

To be considered as passing, the candidate will be required to receive a grade of at least 65% in each portion of the written examination and an average grade of 75% on the entire written and oral examination.

REEXAMINATIONS

Candidates who have failed in any portion of the examination may be admitted to another examination after one year, or within three years, except in such cases as the board may for good and sufficient reason deny a candidate the privilege of reexamination. A candidate who fails one reexamination will be admitted for further examination only after submitting evidence of additional study and preparation. The candidate must give 60 days' notice requesting reexamination and pay a fee of $25 for the written examination and $25 for the oral and practical examination. The examiners conducting the first examination will not be eligible to conduct the reexamination.

CERTIFICATION

After a candidate has met the requirements for eligibility and passed the examinations of the board, a certificate attesting his qualifications in plastic surgery will be issued to him by the board, signed by its officers and having the seal of the board affixed thereto. It shall be the prerogative of the board to determine the fitness professionally and ethically of any candidate for its certificate, and the action or decision of the board regarding the certification of any candidate shall be final.

FEES

The fee for application and examination is $150. Of this sum, $25 must accompany the application and the remaining $125 must be paid when the candidate is notified of acceptance for examination. There will be no refunds. This fee may be increased at the discretion of the board. The board is a nonprofit organization, and the fees of candidates are used solely for defraying the actual expenses of the board. The members of the board serve without remuneration. Because of the limited number of surgeons certified by this board it is necessary for a limited time to request a voluntary annual prorata contribution from diplomates after the first year's certification to help defray expenses.

AMERICAN BOARD OF PREVENTIVE MEDICINE

WALTER L. BIERRING, Chairman, Des Moines, Iowa.
FELIX J. UNDERWOOD, Vice-Chairman for Public Health, Jackson, Miss.
BRIG. GEN. OTIS O. BENSON, Vice-Chairman for Aviation Medicine, Washington, D. C.
ROBERT A. KEHOE, Vice-Chairman for Occupational Medicine, Cincinnati.
GAYLORD W. ANDERSON, Minneapolis.
J. H. BAILLIE, Toronto, Canada.
RICHARD F. BOYD, San Francisco.
MATTHEW R. KINDE, Battle Creek, Mich.
LEROY E. BURNEY, Washington, D. C.
WILLIAM P. SHEPARD, New York.
JAN H. TILLISCH, Rochester, Minn.
CHARLES E. SMITH, Berkeley, Calif.
V. A. VAN VOLKENBURG, Albany, N. Y.
BERTRAM GROESBECK JR., Indianapolis.
JOHN J. PHAIR, Cincinnati.
JAMES H. STERNER, Rochester, N. Y.
A. G. KAMMER, Pittsburgh.
ERNEST L. STEBBINS, Secretary-Treasurer, 615 N. Wolfe St., Baltimore.
JOHN C. HUME, Assistant Secretary, Baltimore.

Consultants

COL. ROBERT L. CALLISON (Army).
CAPT. JAMES J. SAPERO (Navy).
COL. THEODORE C. BEDWELL (Air Force).
JAMES K. SHAFER (Public Health Service).
KATHERINE BAIN (Children's Bureau).
GEORGE R. CALLENDER (Veterans Administration).
BASIL C. MACLEAN, New York.

GENERAL ELIGIBILITY REQUIREMENTS FOR EXAMINATION

1. Good moral character and high ethical and professional standing.

2. Graduation from a medical school in the United States or Canada approved by the Council on Medical Education and Hospitals of the American Medical Association, or from a foreign medical school satisfactory to the board.

3. An internship of at least one year in a hospital approved by the Council on Medical Education and Hospitals of the American Medical Association or in a foreign hospital satisfactory to the board.

4. Licensure to practice medicine in the United States or in the Dominion of Canada.

SPECIAL REQUIREMENTS IN AVIATION MEDICINE

1. Successful completion (after internship) of at least two academic years of graduate study in preventive medicine and aviation medicine, one year of which graduate study shall be in a school of public health accredited for the purpose of such graduate study by the American Public Health Association and one year of which shall be in a school of aviation medicine accredited for the purpose of such graduate study by the Council on Medical Education and Hospitals of the American Medical Association; or training and study deemed by the board to be substantially equivalent to such graduate study.

2. *Residency (after internship) of at least one year of supervised experience in aviation medical practice, which included planned instruction, observation, and active participation in a comprehensive, organized program of aviation medicine.

3. Supervised practice of aviation medicine (after internship) of not less than one year, in addition to 1 and 2 above, of special training in or teaching or practice of aviation medicine.

4. A period (after internship) of not less than two years, in addition to 1, 2, and 3 above, of special training, teaching, research or practice of aviation medicine.

5. Limitation of practice to full-time teaching, research, or practice of aviation medicine.

6. Regular and frequent participation in aerial flight.

Credit for training and experience in public health or aviation medicine while in military service will be considered on an individual basis, depending on the type of service.

SPECIAL REQUIREMENTS IN OCCUPATIONAL MEDICINE

1. Successful completion (after internship) of at least two academic years of graduate study in preventive and occupational medicine in a school of medicine or a school of public health. The schools in which such instruction is provided shall be accredited for graduate study by the Council on Medical Education and Hospitals of the American Medical Association or the American Public Health Association in accordance with the jurisdictions of these accrediting agencies; or training and study deemed by the board to be substantially equivalent to such graduate study.

2. Completion (after internship) of not less than one year, in addition to 1 above, of supervised experience (residency) in occupational medical practice in an industrial or medical organization. This residency shall provide planned instruction, observation and active participation in a comprehensive program of occupational medicine; or a comparable period of experience deemed by the board to be substantially equivalent to such year of supervised experience.

3. A period (after internship) of not less than three years, in addition to 1 and 2 above, of special training in or teaching or practice of occupational medicine.

4. Limitation of practice to full-time teaching, research, or practice of occupational medicine.

FEES

The fee for application and examination is $90, payable as indicated below; additional fees are payable for reexamination as set forth below, but no additional fee is payable for the issuance of a certificate.

Application fee, $15. No application will be considered unless accompanied by the application fee. The application fee is not refundable.

Examination fee, $75. This fee is payable when the candidate is notified of acceptance for examination, and, if paid prior thereto, is not refundable after such notification has been given.

No member of the board has the authority to give informal opinions as to the eligibility of the candidates. The determination of eligibility will be made only by the board after receiving full application information. Each candidate must comply with board regulations in effect at the time the examination is taken, and also those in effect at the time the certificate (if any) is issued, regardless of when the original application was filed. An applicant declared ineligible for admission to examination may refile or reopen his application on the basis of new or additional information within two years of the filing date of his original application without payment of an additional application fee.

Applicants who are declared eligible for examination but who fail to submit to examination within three years of the date of the filing of the application are required to file a new application and to pay a new application fee.

CERTIFICATION IN OCCUPATIONAL MEDICINE WITHOUT EXAMINATION (THE FOUNDERS GROUP)

The bylaws authorize the board, for a limited period of time, to excuse from examination specialists in occupational medicine who have attained high academic rank in an approved medical school or an accredited school of public health or professional position, or by reason of distinguished achievement in the field of occupational medicine are recognized leaders, or have had a minimum of 10 years of distinguished service in the field of

---

* Approval of residency training is in the process of development. Until such time as an adequate program of residency is developed, field training will be evaluated by the board on an individual basis. Information as to approved residencies may be obtained from the Council on Medical Education and Hospitals or from the secretary of the board.

occupational medicine and are considered eligible by the board, whether or not they meet the eligibility requirements previously referred to. Applications for consideration as members of the Founders Group must be received not later than July 1, 1956. The application fee must accompany the application, and the examination fee is payable before certification even though the applicant be excused from examination.

EXAMINATIONS

Examinations will be held from time to time and in various places depending upon need as indicated by applications received. Examinations will ordinarily be held in connection with the annual meetings of one or more of the sponsoring societies and may also be held at other times and at other places so located geographically as to minimize travel for the applicants.

The examination consists of three parts: Part 1 consists of a comprehensive written examination designed to test the knowledge of the applicant in the general field of preventive medicine. Part 2 is a comprehensive written examination designed to test the knowledge of the applicant in the special field in which he requests certification. Part 3 is an oral or practical examination that will usually be held at the completion of the written examinations. An endeavor will be made to adapt the details of the oral or practical examination to each candidate's experience and practice. The examiners will report on each candidate to the assembled board, by which the results of the examination will be considered.

REEXAMINATION

Candidates failing the first examination taken may, upon timely request, be admitted to a second examination within 18 months following the examination failed, upon payment of an additional fee of $15. If the candidate fails the second examination, a period of 11 months must elapse before admission to a third examination. A fee of $25 is required for admission to the third examination. Candidates failing three examinations will not be admitted to any subsequent examinations unless the board so directs.

CERTIFICATION

On satisfactory completion of the examination and proof to the satisfaction of the board that the applicant is eligible for certification, a certificate will be issued to the effect that the person named has been found to be possessed of special knowledge in the field specified in his application. The certificate will be signed by officers of the board and will have its seal affixed. Each certificate remains the property of the board, but the person to whom it is issued shall be entitled to its possession unless and until it is revoked. Any certificate issued by the board may be revoked if evidence, satisfactory to the board is presented that the applicant was not eligible to receive it at the time of examination or issuance, or that he misstated, misrepresented or concealed any pertinent fact, or that his license to practice medicine has been suspended or revoked, or that he has ceased to be engaged in the teaching or practice of the specialty in which he has been certified. The issuance of a certificate to any person does not constitute such a person a member of the board.

AMERICAN BOARD OF PROCTOLOGY

Louis E. Moon, President, Omaha.
R. A. Scarborough, President-Elect, San Francisco.
Harry E. Bacon, Vice-President, Philadelphia.
Garnet W. Ault, Washington, D. C.
Frederick B. Campbell, Kansas City, Mo.
Walter A. Fansler, Minneapolis.
A. W. Martin Marino, Brooklyn, N. Y.
Hyrum R. Reichmann, Salt Lake City.
Robert J. Rowe, Dallas, Texas.
Stuart T. Ross, Secretary, 520 Franklin Ave., Garden City, N. Y.

Associate Member

Clifford E. Hardwick, Portland, Ore.

Advisory Council

Louis A. Buie, Rochester, Minn.
Louis J. Hirschman, Traverse City, Mich.
Curtice Rosser, Dallas, Texas.
George H. Thiele, Kansas City, Mo.

QUALIFICATIONS OF CANDIDATES

General Qualifications and Requirements.—All candidates shall comply with the current regulations of the board, regardless of the time of filing applications. These are as follows:

1. Candidates shall have limited their practice to proctology, shall appear personally before the board, and shall submit to the required examination.

2. They shall deliver to the board an official record of patients hospitalized by them during the year prior to the date of submission of the application if the board requests it.

3. They shall submit a bibliography of papers and books published.

4. They shall possess moral, ethical, and professional qualifications acceptable to the board.

5. They shall possess full citizenship in the country where they practice (limited to countries of North and South America, their possessions and their territories, and the Philippine Islands).

Professional Qualifications.—

1. They shall be graduates of medical schools approved by the Council on Medical Education and Hospitals of the American Medical Association.

2. They shall possess a license to practice medicine in the country of their residence.

3. They shall have completed an internship, preferably of the general rotating type, of not less than 12 months in a hospital approved by the Council on Medical Education and Hospitals of the American Medical Association.

Special Professional Qualifications.—They shall have completed:

1. Two years of approved general surgical residency and two years of approved proctologic residency; or

2. Three years of approved general surgical residency and two years of approved proctologic precepteeship; or

3. Two years of approved general surgical residency and three years of approved proctologic precepteeship.

APPLICATIONS

Each candidate for examination shall submit an application prepared upon the prescribed form, which shall be furnished by the secretary of the board. It shall contain a record of the candidate's premedical and medical training, internships, residencies, precepteeships, other postgraduate study, hospital and dispensary appointments, teaching positions, service in the armed forces, service in federal, state, or local government, membership in medical societies, and any additional information considered valuable by the board. The application shall be signed by two proctologists. It shall be accompanied by two unmounted autographed recent photographs of the candidate, letters of endorsement from appropriate sources, and the application fee. It shall be filed with the secretary not less than 90 days prior to the date of examination.

EXAMINATIONS

Examinations are conducted at times and places determined by the board and are announced in The Journal of the American Medical Association. An average of 75% is the passing grade on all examinations. All examination papers are identified only by numbers assigned to candidates, and the examiners do not know the identity of the examinees.

Part I.—This examination consists of a comprehensive written examination in anatomy, physiology, pathology, bacteriology, biochemistry, and other basic sciences. It is usually held in the spring of the year in several cities of the United States. Candidates who have passed part 1 examinations of the American Board of Surgery or who are diplomates of this board and who have completed required training in proctology may, upon approval of the American Board of Proctology, be excused from taking part 1 of the examinations of the American Board of Proctology.

Part 2.—This examination consists of comprehensive written and oral examinations on the theory and practice of proctology. It includes questions on roentgenologic interpretation and other subjects considered appropriate by the board. Usually this examination is held in the fall of the year in one city of the United States. The oral portion of the examination is conducted by the members of the board or by designated examiners. An attempt is made to ascertain the candidate's knowledge of current proctologic literature, his knowledge of the basic sciences, the extent of his clinical experience, and other qualifications.

Part 3.—This examination is held in the community in which the candidate conducts his professional activities. It may be omitted at the discretion of the board. Candidates required to take part 3 are notified by the secretary and arrangements for the examination are made that are suitable to the candidate and the examiner. The examination shall involve: (1) surgical operations, (2) hospital rounds, (3) hospital and office records, and (4) office practice.

REEXAMINATIONS

A candidate who fails in part 1 or part 2 may be reexamined after one year has elapsed. The act of filing an application for reexamination is the candidate's responsibility. Candidates who have failed a reexamination may petition the board for another examination. With this petition, acceptable evidence of additional preparation shall be submitted.

FEES AND DUES

Fees.—Application fee. A fee of $25 shall accompany the application.

Examination fee. A fee of $150 is due and payable when the candidate is notified that he has been approved to take part 1 or part 2 examinations.

Reexamination fee. A fee of $50 is due and payable when the candidate is notified that he has been approved for reexamination in either part 1 or part 2 examinations.

Reexamination in Part 3.—Candidates for reexamination in part 3 may be held responsible for payment of expenses incurred by the board in conducting the reexamination. No fee shall be returned to the candidate without board approval. All fees shall be made payable to the American Board of Proctology and shall be sent to the secretary.

Dues.—Each diplomate is required to pay a fee of $10 to the board annually for a period of 10 years following certification.

Fees and dues are utilized to defray expenses incurred by board activities.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY

Bernard J. Alpers, President, Philadelphia.
Francis J. Gerty, Vice-President, Chicago.
C. H. Hardin Branch, Salt Lake City.
Henry W. Brosin, Pittsburgh.
Russell N. DeJong, Ann Arbor, Mich.
Knox H. Findley, San Francisco.
Francis M. Forster, Washington, D. C.
William Malamud, Boston.
Frederick P. Moersch, Rochester, Minn.
George N. Raines, Portsmouth, Va.
Paul I. Yakovlev, Boston.
David A. Boyd Jr., Secretary-Treasurer, 102-110 Second Ave., S.W., Rochester, Minn.

APPLICATION FOR CERTIFICATES

An application, in order to be considered at any meeting of the board, must be in the hands of the secretary of the board not less than 90 days before the date of such meeting. A proper application form may be obtained from the secretary. Application may be made for certification in psychiatry or in neurology or in both fields. Applications will be formally considered only when made on the official application blank in such form as may be adopted from time to time by the board and when accompanied by an application fee in such amount as may be fixed by the board.

The secretary of the board, on receipt of an application, shall forthwith make inquiries from those to whom the candidate refers and from such other persons as the secretary may deem desirable and shall verify the candidate's record from the biographical records of the American Medical Association, after which he shall forward the application to the committee on credentials. This committee shall consider the application and other information available and notify the secretary whether the application is accepted. The certification of a candidate in either psychiatry or neurology, or both, shall be approved by a majority of the members of the entire board at any meeting held for such certification.

FORM OF CERTIFICATION

There shall be separate certification in psychiatry and in neurology and two certifications or a combined certification for those qualified in both fields. The certifications shall be in such form as is approved by the board of directors.

GENERAL REQUIREMENTS FOR APPLICANTS

Each applicant for a certificate must establish that:

1. He is a physician duly licensed by law to practice medicine.
2. He is of acceptable ethical and professional standing.
3. He is now a member of the American Medical Association. Exceptions to the foregoing may be made at the discretion of the board for good and sufficient reasons.
4. He has received adequate training in psychiatry or neurology, or both, as a specialty.

CLASSES OF APPLICANTS

Class A.—Applicants who graduated from an approved medical school before the foundation of the board (1934) will not be held to the strict interpretation of the published requirements in formal graduate training. Under such circumstances the board will consider the training and experience of the applicant and decide whether or not he will be admitted to the examinations. After Jan. 1, 1954, for such graduates the board will consider 10 years of full-time acceptable experience in psychiatry or neurology in lieu of the formal training requirements. Should the candidate then apply for supplementary certification, the credentials committee will require five years of additional acceptable experience in the supplementary field.

Class B.—Applicants who graduated from an approved medical school after 1934 shall fulfill the following requirements.

PROFESSIONAL EDUCATION

1. Graduation from a medical school in the United States or Canada approved by the Council on Medical Education and Hospitals of the American Medical Association. In the case of an applicant whose medical training has been received outside the United States and Canada, such training must be satisfactory to the afore-mentioned Council.

2. Completion of a year's internship approved by the same Council in general medicine, general surgery, pediatrics, or a rotating service.

3. The nine month wartime internships will be accepted as an equivalent of one year.

SPECIALIZED TRAINING

Admission to the examination for certification in psychiatry or in neurology requires a total of five calendar years of training and experience, three years of which must be specialized training obtained in approved training centers, plus two years of experience. Admission to the examination for certification in both psychiatry and neurology requires a total of six calendar years of training and experience, five years of which must be specialized training obtained in approved training centers, plus one year of experience. The specialized training may be subdivided into two and one-half years each in psychiatry and neurology or three years in one subject and two years in the other. The required years of experience should be spent in clinical practice with major responsibility for the care of patients.

This training for psychiatrists should include clinical work with psychoneurotic and psychotic patients, combined with the study of basic psychiatric sciences, medical and social psychology, psychopathology, psychotherapy, and the physiological therapies, including a basic knowledge of the form, function, and pertinent pathology of the nervous system. This training should be supervised and guided by teachers competent to develop skill and understanding in the utilization of such basic knowledge in dealing with patients. Mere factual knowledge is not sufficient. This training period should include instruction in the psychiatric aspects of general medical and surgical conditions and the behavior disorders of children and adolescents sufficient to develop practical ability to direct the treatment of such conditions. It should also include collaborative work with social workers, clinical psychologists, courts, and other social agencies. The training program of the candidate for certification in psychiatry should include sufficient training in neurology to enable him to recognize and to evaluate the evidences of organic neurological disease.

The training for neurologists should be based on clinical work with adults and children with neurological disorders, including the neurological complications of medical and surgical conditions. This should be combined with study of basic neurological sciences, neuroanatomy, neurophysiology, neuropathology, and neuroroentgenology. This training should be supervised and guided by teachers competent to develop skill and understanding in the utilization of such basic knowledge in dealing with patients. Mere factual knowledge is not sufficient. This training should include sufficient training in psychiatry to enable the candidate to recognize and to evaluate the common psychiatric reactions.

The board offers the foregoing two paragraphs as an outline of desirable training. If, however, the candidate has evidence of equivalent qualifications of training and experience not in the pattern here formulated, this evidence with appropriate documentary support may be included in his application for evaluation and possible approval by the board.

Candidates seeking certification in both neurology and psychiatry or supplementary certification in one after being certified in the other must submit evidence satisfactory to the board of an additional two years of full-time basic training in the supplementary specialty.

Thus, no candidate is eligible for examination by the board until he has completed at least five years of special training and experience in neurology or psychiatry for a single certificate, or at least six years of special training and experience in neurology and psychiatry for certification in both neurology and psychiatry.

The board will give not more than six months of credit for not less than six months of training in an approved training center for internal medicine or pediatrics in lieu of six months of experience to candidates for the certificate in psychiatry or neurology, but not to candidates for certification in both psychiatry and neurology.

The board will give credit for one year of training in child psychiatry providing it is the third year of the required three years of special training required by the board and providing it is taken in a center approved by this board for training in child psychiatry. After July 1, 1956, training credit for work in the field of child psychiatry may be gained only by participation in a hospital residency training program that is regularly approved. After that date, all independent training approval of psychiatric clinics for children is discontinued.

The list of training programs approved by this board and by the Council on Medical Education and Hospitals of the American Medical Association may be found in the current issue of the Internship and Residency Number of THE JOURNAL.

TRAINING IN THE ARMED FORCES

Credit will be granted for one year of wartime military service in the Army, Navy, Public Health Service, and Veterans Administration. Wartime to this board means Dec. 7, 1941, to Feb. 15, 1946. Further credit for specialized training will be granted only if the candidate has received training in an institution recognized by the Council on Medical Education and Hospitals of the American Medical Association and approved by this board. Time beyond one year spent in the above government agencies may be credited to experience providing the candidate has been regularly assigned to a service in neurology or psychiatry.

Training and experience credit toward requirements for examination will be granted for military duty in present emergency under certain conditions. This policy relates to active military medical duty since July 1, 1950. One year of training credit will be granted for one year spent in full-time psychiatric and/or neurological duties. Additional training credit will be granted for that amount of time spent in approved training programs. Experience credit will be granted for any remaining time spent in full-time psychiatric and/or neurological assignments. Double credit will not be granted for any single period of time. For military duty after Jan. 1, 1954, only experience credit will be granted for full-time psychiatric and/or neurological duties. Training credit will be granted for residency assignments in regularly approved training programs.

EXAMINATIONS

Dates and places of examinations are set by the board at its discretion and shall be announced in THE JOURNAL, in the *American Journal of Psychiatry*, in the *Journal of Nervous and Mental Diseases*, and in the *A. M. A. Archives of Neurology and Psychiatry*.

Though the purpose of the examination is to test the competence of the candidate in psychiatry or neurology or both, it must not be forgotten that both these medical disciplines constitute part of the broad field of general medicine. The board requires some proficiency in neurology on the part of those it certifies in psychiatry, and vice versa, but examines the candidate in accordance with the certificate he seeks. The examinations will be of such type that no adequately trained person will fail, and yet they will be sufficiently searching so that the specialist in fact may be separated from the specialist in name. The practical examination will include the examination of patients under the supervision of the examiner. The manner of examining patients and the reasoning and deductions therefrom will constitute an important part of the examination. Oral and practical examinations will be given in the basic sciences with special regard to their clinical implications. Written examinations may be given at the discretion of the board. The examination for certification in psychiatry will differ from the examination for certification in neurology.

PAYMENT OF FEES

The candidate on filing his application shall accompany it with an application fee of $35 which is not returnable. If a preliminary written examination has been decreed, an additional $25 fee will be required at the time of the applicant's acceptance. When notified by the secretary that he is eligible for the oral and practical examination, the candidate shall send to the secretary an examination fee of $65. A candidate who has been certified in either psychiatry or neurology, and who has been admitted to supplementary examination for the other certificate, shall pay an additional examination fee of $65.

A candidate who has failed in one examination is eligible for reexamination within one year on payment of a reexamination fee of $50. After the year has elapsed he must submit a new application and pay new application and examination fees. If he fails the reexamination, he may, after two years have elapsed, submit a new application and $35 fee, present evidence of further training, and pay an examination fee of $65.

A candidate who fails in one or two subjects is eligible for reexamination in those subjects within one year on payment of a reexamination fee of $50. After the year has elapsed he *must submit a new application* and pay new application and examination fees and repeat the entire examination. If he fails the reexamination, he may apply again for the complete examination after two years on submission of evidence of further training and on payment of an application fee of $35. If admitted to the examination, he must pay a new examination fee of $65.

Any candidate who finds himself unable to attend an examination to which he has been admitted and does not notify the secretary at least six weeks before the date of the examination will forfeit his examination fee. Any candidate who fails to appear for examination within a period of three years following the date of notification of eligibility for examination shall be required to submit a new application and pay the attendant fee. If a candidate dies before his certificate is issued, all fees will be returned to his estate.

AMERICAN BOARD OF RADIOLOGY

H. Dabney Kerr, President, St. Michaels, Md.
D. S. Childs, Vice-President, Syracuse, N. Y.
John D. Camp, Los Angeles.
A. H. Dowdy, Los Angeles.
Ross Golden, Los Angeles.
E. L. Jenkinson, Chicago.
Traian Leucutia, Detroit.
I. H. Lockwood, Kansas City, Mo.
F. W. O'Brien, Boston.
J. W. Pierson, Baltimore.
Douglas Quick, New York.
Leo G. Rigler, Minneapolis.
Laurence Robbins, Boston.
B. P. Widmann, Philadelphia.
B. R. Kirklin, Secretary-Treasurer, Kahler Hotel Building, Rochester, Minn.

CERTIFICATES

A certificate will be issued to each candidate who meets the requirements of the board, to the effect that the holder of the certificate has had adequate training in radiology and has successfully fulfilled the requirements of the board.

A certificate granted by this board does not of itself confer, or purport to confer, any degree, or legal qualifications, privileges, or license to practice radiology. Certificates of the board shall be issued on one of four forms:

1. A certificate to the effect that the applicant has been found qualified to practice radiology in all of its branches.

2. A certificate to the effect that the applicant has been found qualified to practice radiology in one or more of the following special fields: (*a*) roentgenology, (*b*) diagnostic roentgenology. (*c*) therapeutic radiology.

3. A certificate to the effect that the applicant has been found qualified to practice radiological physics in all of its branches.

4. A certificate to the effect that the applicant has been found qualified to practice radiological physics in one or more of the following special fields: (*a*) roentgen-ray and gamma-ray physics, (*b*) medical nuclear physics.

DEFINITIONS

For the purposes of this board, the following definitions are adopted:

1. Radiology is that branch of medicine that deals with the diagnostic and therapeutic application of radiant energy including roentgen rays and radium.

2. Roentgenology is that branch of radiology that deals with diagnostic and therapeutic application of roentgen rays.

3. Diagnostic roentgenology is that branch of radiology that deals with the diagnostic application of roentgen rays.

4. Therapeutic radiology is that branch of radiology that deals with the therapeutic application of roentgen rays, radium, and radioactive isotopes.

5. Radiological physics is that branch of physics that deals with the medical application of roentgen rays, gamma rays, radioisotopes, nuclear reactions, and particle accelerators.

6. Roentgen-ray and gamma-ray physics is that branch of radiological physics that deals with roentgen rays and gamma rays.

7. Medical nuclear physics is that branch of radiological physics that deals with radioisotopes, nuclear reactions, and particle accelerators.

GENERAL REQUIREMENTS AND QUALIFICATIONS

Each applicant for admission to the examination for a certificate in radiology shall be required to present evidence that he has met the following standards:

1. Satisfactory moral and ethical standing in the profession.

2. A license to practice medicine in the state or county in which he resides.

3. The applicant holds himself out to be a specialist in radiology or one of its branches as defined under "definitions" and devotes his time to the practice of radiology or one of its branches.

4. He is a citizen of the United States or Canada. Candidates from other countries must be permanent residents of that country and citizens thereof.

PROFESSIONAL EDUCATION

1. Graduation from a medical school recognized by the Council on Medical Education and Hospitals of the American Medical Association.

2. Completion of an internship of not less than one year in a hospital approved by the same Council.

SPECIAL TRAINING

1. After completion of the internship there shall be a period of special training in radiology of not less than three years in clinics, hospitals, or dispensaries recognized and approved by the American Board of Radiology and the Council on Medical Education and Hospitals of the American Medical Association as competent to provide a satisfactory training in radiology. This period of specialized training shall include:

(*a*) Graduate training in pathology, radiation physics, and radiobiology. A period of six months full-time training in pathological anatomy is recommended but where this is not possible to arrange, the student during his three-year training period, may, by attending pathological conferences and postmortem examinations, and by studying removed tissues, receive adequate training in pathology. It is recommended that radiation physics be taught by a combination of didactic lectures, practical examples, and direct clinical demonstrations.

(*b*) An active experience (residency) of not less than 30 months in an institution, the radiological department of which is recognized and approved by the American Board of Radiology and the Council on Medical Education and Hospitals of the American Medical Association as capable of providing satisfactory training.

(*c*) Examination in the basic sciences of radiology as well as the clinical aspects thereof. These examinations should be given by the student's instructors in order to allow those responsible for his training to certify to the board that he is adequately prepared.

APPLICATIONS

The board desires to appraise the candidate's educational opportunities (premedical, medical, and radiological), the ability of his instructors, his hospital and teaching positions, his original investigations, his contributions to radiological literature, his membership in medical societies, and his local and general reputation.

For this purpose, application must be made on a special blank which may be obtained from the secretary. No application will be considered unless made on the regular application blank. This application shall be forwarded with the required data, two unmounted photographs, and the fee of $100 at least six months before the date of the examination.

FEE

A fee of $100 must accompany each application blank. This fee will not be returned, and no application will be considered until the fee is received. This fee has been carefully computed and is used entirely for administrative purposes. As the number of candidates decreases, it may become necessary to raise the fee.

EXAMINATIONS

Each year the board will hold two examinations. The first will be in the spring and the second examination will be held in conjunction with the annual meeting of the American Roentgen Ray Society or the Radiological Society of North America.

For the present, examinations consist of practical and oral examinations, although written examinations may be added later. The examinations are designed to test the candidate's fitness to practice radiology or one of its branches as a specialty. The board will endeavor to adapt this examination to the candidate's experience and years of practice. It will try especially to ascertain the breadth of his clinical experience, his knowledge of the basic sciences of radiology, and likewise his knowledge of the recent literature on radiology, and his general qualifications as a specialist in this branch of medicine.

The examination consists of tests in film interpretation and an oral examination in pathology, physiology, radiophysics, and radiobiology, as well as the clinical application of roentgen rays, radium, and radioactive isotopes. The applicant is also examined in "professional adaptability," in an attempt to ascertain his attitude toward his fellow practitioners and his patients.

Whenever an applicant fails to pass the examination, the board, if requested, will make suggestions as to suitable courses of instruction for the purpose of overcoming his deficiences.

REEXAMINATIONS

If the candidate fails in the first examination he will be admitted to a second examination after one year has elapsed, but not after more than three years. He must give 90 days' notice of his intention to appear for reexamination and pay an additional fee of $50. If a candidate who has failed does not appear for reexamination before the expiration of three years, he will be required to make a new application and pay an additional fee of $100.

A candidate having failed twice may, after one year has elapsed, file a new application, which must be accompanied by the fee of $100.

AMERICAN BOARD OF SURGERY

John D. Stewart, Chairman, Buffalo.
John H. Gibbon Jr., Vice-Chairman, Philadelphia.
William A. Altemeier, Cincinnati.
Joel W. Baker, Seattle.
Michael E. DeBakey, Houston, Texas.
J. Englebert Dunphy, Boston.
Clarence E. Gardner Jr., Durham, N. C.
Frank Glenn, New York.
Gustaf E. Lindskog, New Haven, Conn.
William K. Livingston, Portland, Ore.
Walter G. Maddock, Chicago.
Carleton Mathewson Jr., San Francisco.
James D. Rives, New Orleans.
Harris. B. Shumacker Jr., Indianapolis.
William H. Snyder Jr., Los Angeles.
John M. Waugh, Rochester, Minn.
John B. Flick, Secretary-Treasurer, 225 S. 15th St., Philadelphia 2.
Cletus W. Schwegman, Associate Secretary, Philadelphia.
John J. McKeown Jr., Assistant Secretary, Philadelphia.

GENERAL QUALIFICATIONS

1. Moral and ethical standing in the profession and in the community which is satisfactory to the board.
2. Engagement in the practice of surgery.

PRELIMINARY TRAINING

1. Graduation from an approved medical school in the United States or Canada or from medical schools acceptable to the board in other countries.
2. Completion of an internship (straight or rotating) of not less than one year in a hospital approved by the Council of the A. M. A. or its equivalent in the opinion of the board.

SPECIAL TRAINING

The American Board of Surgery is guided by the evaluation of residency training programs made by the conference committee on graduate training in surgery.

The board interprets the term "general surgery" in a comprehensive manner and expects candidates to have knowledge of the basic principles applied in the treatment of fractures, trauma, head injuries, and of the more common procedures in plastic, gynecologic, orthopedic, thoracic, and urologic surgery. Some elasticity in the training programs will be allowed individuals with preference for specialized fields, experimental surgery, or research. In such programs the integration of basic sciences, particularly pathology, with clinical training is superior to formal courses.

Requirements for examination are subject to change and in each case are as published in the board's most recent Booklet of Information at the time application is submitted.

GROUPS 1 AND 2

The requirements for examination may be fulfilled by either of the two programs outlined below. Both of these educational programs are considered to be minimal in attaining their purposes.

The board may, at its discretion, require that a satisfactory operative report be filed before the candidate's eligibility for examination is considered. Such a report may be made by a member of the board, Founders Group, or one certified by examination designated to be present during a major operative procedure performed by the candidate.

Group 1.—Completion of a graded residency in surgery of at least four years in an institution or institutions acceptable to the board and approved for four years of training by the conference committee on graduate training in surgery. The final year of the program must have been spent in the capacity of senior or chief resident in surgery.

If the hospital residency training is for a longer period than four years the candidate who completes four years without assuming the responsibilities of the final year cannot be considered in the Group 1 category. Such a candidate must qualify as in Group 2 after a total of at least five years, one year of which may be spent in practice limited to surgery carried out under acceptable supervision.

Credit will be granted for surgical internship to a candidate who has completed one other year of acceptable internship when the surgical internship is part of a graded residency approved for four years by the conference committee.

Group 2.—Completion of a graded residency in surgery of at least three years in an institution or institutions acceptable to the board and approved for three years of training by the conference committee on graduate training in surgery. The final year must have been spent in the capacity of senior or chief resident in surgery.

Credit will be granted for surgical internship to a candidate who has completed one other year of acceptable internship when the surgical internship is part of a graded residency approved for three years by the conference committee.

Two additional years of training beyond the three years of residency to complete a total of five are necessary to meet the requirements for examination. These may have been spent (*a*) in practice limited to surgery carried out under acceptable supervision, (*b*) in the study of surgery and the basic sciences in an approved graduate school of medicine, (no more than one year's credit is granted for work in basic sciences), and (*c*) in surgical training acceptable to the board in the federal services.

By "acceptable supervision" is meant an arrangement with a preceptor suitable to the board who will assume responsibility for the candidate's further training. The supervising surgeon will be required to inform the board in writing of his acceptance of the responsibility. The supervising surgeon must vouch for the candidate's integrity, surgical judgment, and technical skill. Sufficient operative work performed by the candidate under supervision to fortify residency training must be attested to by the preceptor in a statement submitted to the board at the time the candidate makes application for examination. Before considering eligibility of the candidate for examination the candidate will be required to submit to the board a list of the operative procedures performed by him during the period of supervised practice of surgery. The acceptance of supervised practice in the fulfillment of part of the board's requirements is contigent upon the candidate having had adequate clinical opportunities with considerable responsibility in the care of patients, including the performance of major operative procedures under supervision.

The study of surgery and the basic sciences in an approved graduate school of medicine must be full time and extend over a period of not less than nine months. No more than 12 months' credit will be extended for such study. Six months' credit may be allowed for a single basic science such as pathology, physiology, or anatomy. Credit not to exceed one year may be extended for surgical research. Such graduate work will not be credited as part of a three year residency program.

BASIC SCIENCES

A fundamental concept of an approved residency in general surgery requires that the program provide for properly organized, integrated and progressively graded clinical training in the specialty. This concept requires a continuity of clinical experience under the supervision of the surgical staff of the hospital or hospitals in which such training is conducted. Accordingly, the American Board of Surgery while recognizing the value of formal courses in the basic sciences, will not accept these courses as part of a three or four-year program, in lieu of clinical experience. When provision is made for the resident to attend such courses, they will be accepted by the American Board of Surgery as credit toward the practice requirement, in addition to an approved three-year residency (Group 2 candidates). An approved four year residency may include a research project or an assignment to a basic science department such as pathology provided this is an integral part of the residency program. The final year of a four year residency, however, must be spent in clinical surgery in the parent institution.

MILITARY CREDIT

Credit may be extended to those candidates who have served in military hospitals other than those approved for residency training provided that the candidate has had a satisfactory surgical assignment with adequate and diversified clinical materal and provided further that his work in surgery is carried out under the supervision of a surgeon acceptable to the board. Any credit extended in the latter category will be considered preceptorship credit and not residency credit.

LICENSE TO PRACTICE

The board requires, prior to issuance of a certificate, that candidates who are citizens of the United States or Canada have a valid license to practice in the nation of permanent residence except in those situations in which a license to practice is not required, such as the practice of surgery by commissioned officers in the Army, Navy, or public health services of these countries.

REQUIREMENTS FOR FOREIGN-BORN AND FOREIGN-TRAINED APPLICANTS

Candidates must have completed at least the three year residency requirements in an approved hospital in the United States or Canada. In addition, they are required to have a valid license to practice in the nation of their permanent residence. The examination committee may, in individual instances, accept foreign training as the equivalent of acceptable residency training in the United States.

APPLICATIONS

Prospective candidates for examination by the board should carefully read the board's requirements as set forth in its Booklet of Information. If, after becoming familiar with the requirements, the candidate needs advice as to his training, such may be had by writing to the board's office. When a candidate's training seems to meet the requirements, an application blank will be mailed. The processing of the completed application requires a minimum of three months by the board's office. The candidate will then be notified by the secretary as to his acceptability for examination, his deferment, or his ineligibility.

The eligibility of a candidate whose training in some respects does not conform to requirements published above will require the action of the examination committee of the board, which may delay the candidate's notification of acceptability. Every candidate's final acceptability for examination is based not only upon the evaluation of his training qualifications, but upon information available to the board concerning his professional ability as a surgeon and his ethical standing in the community.

Candidates are required to complete their training and meet all other requirements of the board before submitting an application for examination. Candidates are notified of their eligibility for the part 1 examination as soon as their applications have been approved and are sent a list of centers from which they may select the center of their choice.

THE FOUNDERS GROUP

The Founders Group, to which were admitted those who had already amply demonstrated their fitness as trained specialists in surgery, was closed in January, 1940.

EXAMINATIONS

The qualifying examination is divided into part 1 (written) and part 2 (clinical, bedside, and laboratory). In both of these, as previously stated, a knowledge of the practical application of the sciences fundamental to surgery is required.

Part 1.—The examination is given simultaneously in as many centers throughout the United States as the board may determine suitable for the purpose and in certain military centers abroad. It is held twice a year—in the spring and in the fall.

Requests for a particular center should be made to the board's office well in advance of the date set for examination.

The examination in part 1 is of the objective, multiple-choice type, and covers a half-day session. This examination is designed to cover general surgical problems including the application of the basic sciences of surgery to these problems. Questions are of various types, and include case histories, questions indicating ability in judging cause and effect, and questions illustrating comparisons and relationships. The tests are written by members of the board with the aid of test specialists of the educational testing service.

Part 2.—The examination is conducted by members of the board and selected diplomates in various centers in the United States.

The part 2 examination is oral and practical. The schedule is arranged somewhat as follows:

8:15 A.M.—Registration

9 A.M. to 1 P.M.—Clinical surgery (diagnosis, management, and the application of physiology, biochemistry, and bacteriology). The interpretation of roentgenographic studies also may be included.

2 to 5 P.M.—Applied anatomy and surgical pathology.

GRADES

A candidate must receive a grade of 75% in part 1, and a grade of 75% in all three subjects, clinical surgery, surgical pathology, and applied anatomy in part 2, to be entitled to the board's certificate.

REEXAMINATIONS

Part 1.—Candidates who fail part 1 are required to wait one year before becoming eligible for reexamination.

Part 2.—Candidates who fail part 2 in clinical surgery or who fail both anatomy and pathology are required to wait one year before establishing eligibility for reexamination. Those who fail only anatomy or pathology are required to wait six months. The board expects that during this period the candidate will make a reasonable effort to prepare himself in the subject or subjects in which he has failed.

Should a candidate fail a reexamination in part 1 or part 2, the examination committee will consider an appeal for further examination privileges after the lapse of two years, provided satisfactory evidence of further preparation for examination is submitted. The board, however, for good and sufficient reason, may deny a candidate the privilege of further examination.

FEES

The fee for examination is $150 payable as follows: $25 for registration, $50 for part 1, and $75 for part 2.

Candidates are required to pay a fee of $50 for reexamination in part 1, $75 for reexamination in part 2, in its entirety, and $25 for reexamination in a single subject.

This board is a nonprofit organization. All fees will be used, after a reasonable amount is set aside for necessary expenses, to aid in improving existing opportunities for the training of surgeons. The members of the board serve without remuneration.

CERTIFICATE

After meeting the requirements for eligibility and passing the examinations, a certificate attesting to a candidate's qualification in surgery will be issued by the board, signed by its officers.

REVOCATION OF CERTIFICATE

Any certificate issued by the board shall be subject to revocation at any time in case it shall determine in its sole judgment, that a candidate who has received a certificate was not properly qualified to receive it.

CERTIFICATION IN THORACIC SURGERY

Diplomates of the American Board of Surgery wishing to become certified in thoracic surgery are advised to communicate with the secretary of the Board of Thoracic Surgery, Dr. William M. Tuttle, 1151 Taylor Ave., Detroit 2. This board is an affiliate of the American Board of Surgery.

BOARD OF THORACIC SURGERY

(An Affiliate of the American Board of Surgery)

Richard H. Sweet, Chairman, Boston.
William E. Adams, Vice-Chairman, Chicago.
Thomas H. Burford, St. Louis.
O. Theron Clagett, Rochester, Minn.
Michael E. DeBakey, Houston, Texas.
Joseph W. Gale, Madison, Wis.
Julian Johnson, Philadelphia.
John C. Jones, Los Angeles.
Paul C. Samson, Oakland, Calif.
Robert H. Wylie, New York.
William M. Tuttle, Secretary-Treasurer, 1151 Taylor Ave., Detroit 2.

FUNCTIONS OF THE BOARD

1. To select Founder Members. For this group, surgeons of the United States and Canada were chosen who had made meritorious contributions to thoracic surgery.

The Founders Group was kept open for two years after organization of the board.

It was officially closed April 14, 1951.

2. To conduct examinations of satisfactory candidates who seek certification by the board.

3. To improve the opportunities for the training of thoracic surgeons.

4. To set up principles of education to guide young surgeons who desire to prepare themselves for proficiency in thoracic surgery.

5. To issue certificates of qualification to all those meeting the board's requirements.

REQUIREMENTS

1. Certification by the American Board of Surgery.

2. Two years' training in thoracic surgery approved by the Board of Thoracic Surgery, or meritorious contributions to thoracic surgery. One of these two years may be spent during the four years of training in surgery required by the American Board of Surgery.

3. Written, oral, and practical examinations.

DEFINITION OF WHAT IS CONSIDERED ACCEPTABLE TRAINING IN THORACIC SURGERY

To qualify for the examination in thoracic surgery, the candidate shall have had two years of training in an active, well-integrated thoracic surgical clinic or clinics, or the equivalent amount of thoracic surgical training, on a mixed service consisting of thoracic and nonthoracic surgical cases. Adequate training in both the tuberculous and nontuberculous aspects of thoracic surgery is expected. In order to obtain this objective, combined residencies between institutions of different types may be advantageous. It is also required that the candidate be familiar with the basic sciences as related to thoracic surgery. Under exceptional circumstances certain surgeons may, by virtue of recognized proficiency in the surgical treatment of thoracic diseases, qualify for the examination at the discretion of the board.

APPLICATIONS

Prospective candidates desiring to apply for examination should consider whether they are able to meet the minimum requirements of the board. They should then submit a letter to the secretary's office outlining briefly their training and experience in thoracic surgery and should ask for an application form. An application form will not be sent unless evidence is submitted in a letter indicating that the prospective applicant appears to meet the minimum requirements.

EXAMINATIONS

The qualifying examinations are divided into two parts. Part 1 is written, and part 2 is an oral examination in clinical surgery, roentgenogram interpretation, and pathology.

Part 1.—This examination will be given simultaneously at least once a year in as many centers throughout the country as the board may determine suitable for this purpose.

Part 2.—In order to be eligible for part 2 a candidate must have successfully completed part 1. Examinations in part 2 are conducted in certain centers of the country selected by the board. After having passed part 1, a candidate must appear for part 2 within two years unless excused for due cause by the board.

REEXAMINATIONS

Those persons who fail part 1 or part 2 will be required to wait one year before they can retake the part which they failed. Those who fail twice will be required to wait for a period of two years. Candidates who are unsuccessful after three attempts will be required to wait three years before requesting reconsideration. The board may at its discretion deny the candidates the privilege of reexamination.

Candidates declared eligible but who fail to exercise the examination privilege within three years of the date of filing the application will be required to file a new and current application and pay a new examination fee. Also, a candidate who has failed in an examination (part 1 or part 2) and who does not apply for reexamination within three years shall be required to make a new application and pay a new examination fee.

FEES

For the special examination in thoracic surgery and the issuing of a certificate, the fee will be $100. Fifteen dollars of this fee is to accompany the application and will be considered as a registration fee. It is nonreturnable to the applicant in case he is disapproved for examination.

The fee for reexamination will be $50.

AMERICAN BOARD OF UROLOGY

EDGAR BURNS, President, New Orleans.
GRAYSON CARROLL, Vice-President, St. Louis.
A. I. DODSON, Richmond, Va.
HARRY CULVER, Chicago.
THOMAS D. MOORE, Memphis, Tenn.
RUBIN FLOCKS, Iowa City.
DONALD A. CHARNOCK, Los Angeles.
WILLIAM P. HERBST, Washington, D. C.
WILLIAM NILES WISHARD JR., Secretary-Treasurer, Indianapolis.
MRS. RUBY L. GRIGGS, Assistant Secretary, Minneapolis.
Office of the Secretary-Treasurer, 30 Westwood Rd., Minneapolis 16.

Emeritus Members

WILLIAM F. BRAASCH, Rochester, Minn.
T. LEON HOWARD, Denver.
CLARENCE G. BANDLER, New York.
GEORGE GILBERT SMITH, Brookline, Mass.
CHARLES C. HIGGINS, Cleveland.
ROGER GRAVES, Boston.
GILBERT J. THOMAS, Santa Monica, Calif.
GEORGE F. CAHILL, New York.
A. I. DODSON, Richmond, Va.

PURPOSES OF THE BOARD

The first objective of the American Board of Urology is to render better service to the public by ascertaining the competency of any physician or surgeon who is specializing, or who wishes to specialize, in the field of urology. It will investigate the curricula of medical schools and will encourage adequate facilities for graduate instruction in urology, thus elevating the standards and advancing the cause of urology.

FUNCTIONS OF THE BOARD

A. The board will arrange and conduct examinations testing the qualifications of volunteer candidates.

B. The board will grant and issue certificates to accepted candidates duly licensed by law. It also holds the power to revoke the same.

C. The board will endeavor to serve the public, hospitals, medical schools, medical societies, and practitioners of medicine and surgery by preparing lists of urologists whom it has certified.

LIMITATIONS OF FUNCTIONS OF THE BOARD

The conferring of the degrees doctor of medicine or bachelor of medicine remains with the universities, where it belongs. This board makes no attempt to control the practice of urology by license or legal regulation and in no way interferes with or limits the professional activities of any duly licensed physician.

A list of approved residencies for training in urology may be found in the Internship and Residency Number of THE JOURNAL of the American Medical Association.

Training programs in urology are approved by a residency review committee consisting of members from this board and representatives from the Council on Medical Education and Hospitals of the American Medical Association.

REQUIREMENTS FOR ALL APPLICANTS

A. Application for certification must be made on a special form. This will be provided by the secretary and must be returned to him accompanied by other required data and credentials and by $50 of the examination fee.

B. The applicant must have graduated from a medical school of the United States or Canada recognized by the Council on Medical Education and Hospitals of the American Medical Association and must have completed an internship of not less than one year in a hospital approved by the same council.

Requirements of graduates of foreign medical schools shall conform to and be similar to the requirements as demanded of the applicants for the accepted medical schools in the United States and Canada. Such applications will be considered by the full board on individual merits.

C. The applicant must establish in a manner satisfactory to this board that he is a physician duly licensed by law to practice medicine, that he is of high ethical and professional standing, and that he is a member of the county district or territorial medical society of his place of practice.

D. The applicant must establish that he has received special graduate training as follows:

1. An approved internship of at least one year.
2. One year in the basic sciences or clinical studies basic to urology, or one year residency in general surgery or internal medicine.
3. An approved graduated three year residency in urology leading to competency in all its phases.

E. The applicant must have an additional period of not less than two years in the practice of urology in the city of his office or place of practice.

F. The applicant must assure the board that he is engaged in the practice of urology and intends to continue to be so engaged.

G. Applicants whose postinternship training started prior to July 1, 1955, will be required to have a total of three years residency, two years of which must have been in approved graduated training in urology and one year preceding in studies consisting of clinical studies basic to urology. These may consist of general surgery or internal medicine.

Applicants who started postinternship training after July 1, 1955, but before July 1, 1957, may fulfill their requirements by completing a four year training consisting of:

1. One year in general surgery, a two year approved graduated urologic residency and one initial year in the basic sciences or clinical studies underlying urology, or
2. One year in general surgery, two years formal training in urology, described in 1 above, and one year of credit for two years of a preceptorship, approved by the board.

FEE

The examination fee is $150. (This fee will be increased when the expense of the examinations and other activities of the board demand.) Fifty dollars must accompany the application. If, upon investigation, an applicant is found lacking in any of the requirements stated above, he will be notified that he is ineligible for examination. One hundred dollars must be paid when the application has been processed. Neither fee shall be returnable in any event.

Applications for certification shall be examined by the credentials committee and reviewed by the board. When additional data are required to complete the application, these will be requested by the secretary.

If a candidate fails, he will be permitted a second examination after one year or within three years without additional fee, but he must give sixty days' notice of his intention to appear for reexamination. After an applicant has failed twice he may file a new application and pay a second fee.

A candidate who has been failed twice in any part of the examinations may be required to have additional training in accordance with recommendations from the credentials committee and from the full board before he may be permitted further examination.

REQUIREMENTS FOR CERTIFICATION

The requirements for certification include: evidence of hospital practice including the presentation of reports of 25 representative (not necessarily consecutive) major urologic cases from practice, which must contain all items essential for diagnosis, therapy, prognosis, results of treatment, etc.; a written examination; pathology and oral clinical examinations.

A. Evidences of Hospital Practice and Case Reports:

An index, in consecutive order, of all major and minor urologic surgery (including endoscopy) done during the last two years of practice must be presented. This index must be verified by the various hospital administrators.

The reports of 25 major urologic cases must be representative reports from private practice. These reports must be typewritten on 8½ by 11 paper and in duplicate, but need not be on any special form. Please file the duplicate in your own office. This second copy will be called for when and if it is needed.

Complete index lists must accompany the reports. If they are obtained from more than one hospital a separate index list of each group should be provided. These lists must state the operator's name at the head of each page, the name (or initials) of the patient, the hospital number, and the name and date of operation. Statements from the superintendents of the hospitals attesting that the candidate was the operator must be included.

The applicant must personally prepare the case reports, remembering that they are documentary evidence of his ability and that the material in them and the manner of presentation are important evidences of his competence as a urologist.

The deadline for the receipt of case reports each year is Sept. 1. The case reports should be prepared as follows:

1. Heading, including identification of patient, hospital number and name or initial, age, marital status, sex, occupation, diagnosis, dates of hospitalization, date and name of operation, and outcome.
2. Complete history, including chief complaint, present and past history, family history, review of systems, etc.
3. Complete physical examination, including temperature, pulse, respiration, and blood pressure.
4. Initial laboratory and x-ray examinations.
5. Admitting diagnosis, based on above, with reasons for making this diagnosis.
6. Indications for further management and description of same in chronologic order together with findings and outcome, as they occurred. This should include detailed description of all subsequent laboratory and x-ray findings, final preoperative diagnosis and reasons for same, and major and minor surgical procedures. This should include also a detailed description of all other treatment and findings such as administration of drugs and fluids, morbidity, complications, consultations, use of special drainage, etc. A detailed description of the postoperative course including complications and outcome should be given. If autopsy is done this should be reported.
7. A follow-up of patient's course after dismissal from the hospital.
8. Final summary of the case. This must include the candidate's interpretation of the record in terms of pathology; the basis for the diagnosis; the facts that determined the treatment prescribed, whether surgical or otherwise; the course of treatment to be pursued following discharge from the hospital or clinic; and a critical discussion of the knowledge gained from the proper handling of the case, or from errors made (if any) in the diagnosis and method of treatment.
9. The entire record should be compiled as chronologically as possible and must contain dates of all data.

B. Written Examination:

The written examination is designed to test the candidate's preparation in and his knowledge of the whole field of urology, including the subjects: clinical urology, pathology, anatomy, physiology, embryology, bacteriology, physiological chemistry, and endocrinology. These may be held on certain dates simultaneously in different parts of the country at places convenient for candidates.

C. Pathology:

The examination in pathology will consist of the identification of gross specimens and of sections of tissue observed through the microscope. It will be held at the time of the oral examination.

D. Oral-Clinical Examination:

This will consist of discussions of common urologic conditions. The subjects forming the basis of this examination are urography; diseases of the genital organs, including the prostate; diseases of the urinary bladder; and diseases of the ureters and kidneys. The examination may deal directly with data found in the case reports which the candidate has submitted. It will ascertain the candidate's familiarity with recent literature, the breadth of his clinical experience, and his general qualifications for practice in the specialty of urology.

The professional adaptability of each candidate will be investigated in an attempt to determine his ethical conduct and his attitude toward his patients and fellow practitioners.

FINAL ACTION OF THE BOARD

Final action concerning each applicant is made by the entire board and is based on the applicant's training, his professional record, his attainments in the field of urology, and the results of the examinations. Any competent urologist with the required training will have no difficulty obtaining the board's certificate. This board is organized not to prevent qualified urologists from obtaining certificates but to assist them in becoming recognized in their communities as men competent to practice in the special field of urology.

REVOCATION OF CERTIFICATE

Certificates issued by this board are subject to the provisions of the articles of incorporation and the bylaws. According to article IX, section 4, of the bylaws, "Each certificate shall be subject to revocation in the event that:

A. The issuance of such certificate or its receipt by the physician so certified shall have been contrary to, or in violation of, any provision of the certificate of incorporation of this, the American Board of Urology, or of the bylaws; or

B. The physician or party certified shall not have been eligible to receive such certificate, irrespective of whether or not the facts constituting him so ineligible were known to, or could have been ascertained by, the directors of the board at the time of the issuance of such certificate; or

C. The physician or party so certified shall have made any mis-statement of fact in his application for such certificate or in any other statement or representation to the board or its representatives; or

D. The physician so certified, at any time while continuing to practice, shall cease to practice urology; or

E. The physician so certified shall at any time have neglected to maintain the degree of competency in the practice of the specialty of urology as set up by the board, and shall refuse to submit to reexamination by the board.

The board of trustees of this corporation shall have the sole power, jurisdiction, and right to determine and decide whether or not the evidence or information before it is sufficient to constitute one of the grounds for revocation of any certificate issued by this corporation. The board of trustees may, however, in its discretion, require any physician so certified to appear before the board of trustees or before any one or more of them or before any individual or individuals designated by the board of trustees, upon not less than 20 days written notice, and to show cause, at the time and place specified in such notice, why his certificate should not be revoked upon any one or more of the above-described grounds specified in such notice. The failure of any physician so notified to appear as required in such notice, without due excuse deemed sufficient to the board of trustees, shall constitute, ipso facto, cause for revocation of his certificate. The decisions of the board of trustees relating to all matters under this section 4 shall be final and binding.

Information regarding the Advisory Board for Medical Specialties and the 19 Examining Boards for Medical Specialties, which appears in this issue, and the data included in the Internship and Residency Number, Sept. 24, will be published in the Directory of Approved Internships and Residencies as a separate reprint.

ESOPHAGEAL VARICES

Esophageal varices develop secondarily to partial or complete obstruction of the portal blood flow at the junction of the esophagus and cardia of the stomach between the coronary vein, a branch of the portal circulation, and the esophageal veins, branches of the azygos vein, of the systemic circulation. Portal hypertension may be one of two types, intrahepatic or extrahepatic, or a combination of both. Apparently, the portacaval shunt created by the natural anastomosis of the two systems at the gastroesophageal junction is inadequate to prevent increased intraportal tension and the consequent development of esophageal varices.

Chiles and his co-workers [1] at the Mayo Clinic found that, in a study of 80 cases of ruptured esophageal varices in which hemorrhage led to death, rupture was caused in 39% of the cases by the increased hydrostatic pressure within the varix and in 50% by ulceration of the varix. In the majority of the cases, ulceration appeared to be a complicating factor that hastened the impending perforation of the vein. Hemorrhage from the esophageal varices, particularly in portal hypertension with cirrhosis of the liver, is a frequent cause of death, second only to peptic ulcer as a cause of massive upper gastrointestinal bleeding.

Attempts at lowering the tension in the portal system by ligation of the splenic artery, the hepatic artery, and splenic and hepatic arteries proved unsatisfactory in controlling the bleeding and at the same time it carried a high operative risk. The method of compressing the varices by balloon tamponade, first reported by Westphal in 1930 as quoted by Linton and Warren [2] and by Rowntree [3] in 1947 proved to be more successful. Thus, Sengstaken and Blakemore [4] reported in 1950 on 30 patients with an acute hematemesis successfully treated with a nasogastric tube bearing a reinforced balloon. The balloon tamponade, Linton and Warren point out, is also useful in differentiating the source of bleeding, since, if the cardioesophageal tamponade controls the bleeding, then the source of it is esophageal varices and not a peptic ulcer of the stomach or duodenum. The removal of the tube, however, will not infrequently give rise to further bleeding. Linton and Warren, therefore, regarded this method as a temporary means to be followed by transesophageal suture of the varices. Immediate or early suturing of the ruptured varix permits adequate time in which to prepare the patient for the major surgical intervention of constructing some type of portacaval shunt.

Crile [5] considered suturing the esophageal veins as a definitive treatment of bleeding varices. He reported in 1950 on seven patients with severe bleeding from esophageal varices successfully treated by the operation of transesophageal ligation of the varices. He believed that this treatment was adequate in controlling bleeding in the extrahepatic blocks of the portal or the splenic veins. Most workers in this field feel that the definitive treatment of bleeding esophageal varices should be one capable of permanently lowering the tension in the portal system. This could be accomplished by anastomosis between the portal vein and the inferior vena cava or by an end-to-side anastomosis of the splenic vein to the renal vein. Under these circumstances, a large volume of blood will pass from the relatively high-pressure portal system into the low-pressure caval system via the shunt. Linton [6] reported on 77 patients who survived the formation of a portacaval shunt; 8 of these patients are now dead, and the remaining 69 (97%) are alive and in good health. Blakemore [7] reported an operative mortality of 17.8% for a series of 140 cases of shunt operation.

Cooley and DeBakey [8] proposed a rather radical operation consisting of an extensive subtotal resection of the esophagus as a definitive treatment for bleeding esophageal varices. The operation was carried out on three patients, two of whom have survived and are doing well.

Whatever surgery is contemplated, the surgeon must bear in mind the risk presented by the functional status of the liver and the deleterious effect on the liver of the long-standing portal hypertension. The improvement in the operative results in the last few years is due to achievements in the medical treatment of cirrhosis of the liver and the knowledge that a cirrhotic liver fortified with proteins, carbohydrates, and vitamins, if protected against anoxia, is far more resistant to decompensation following surgery than a liver not so supported. The availability of the whole blood plasma and human albumin for the correction of anemia, restoration of blood volume, restitution of depleted proteins, achievement of potential control of infection, and control of blood clotting are important factors favoring success with venous shunt procedures.

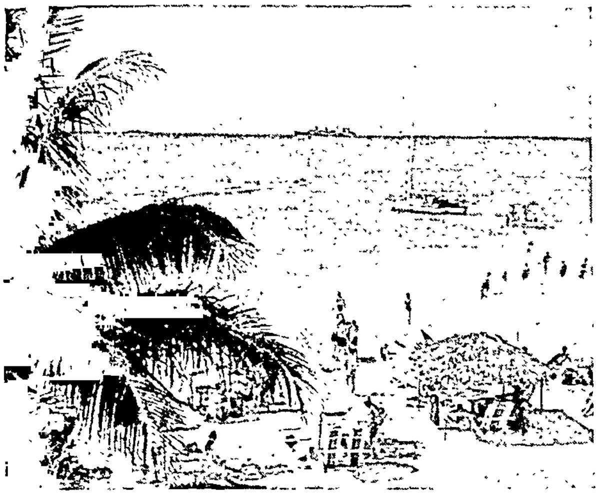
ORGANIZATION SECTION

INVITATION TO NASSAU

Members of the American Medical Association have been invited to meet with the Bahamas Medical Association at the Jungle Club in Nassau on Wednesday, Dec. 7, following the A. M. A. Clinical Meeting in Boston. An official tour to Nassau has been arranged for members of the American Medical Association for the week of Dec. 3-10, permitting physicians to accept the Bahamian invitation. Arrangements for the tour have been made cooperatively by United Air Lines, British Overseas Airways Corporation, Nassau Development Board, and International Travel Service, Inc. (Chicago). Tour folders are available upon request by writing to A. M. A. Nassau Tour Headquarters, 35 E. Monroe St., Chicago 3. The itinerary for the official tour to Nassau is as follows:



Paradise Beach on Hog Island across Nassau Harbor.

Friday, Dec. 2. Bon voyage buffet luncheon in the Bay State Room of Boston's Hotel Statler, followed by an afternoon flight to New York. Members of the tour will stay at the Waldorf-Astoria Hotel.

Saturday, Dec. 3. Departure at noon on a British Overseas Airways Stratocruiser, the Bahamian, to arrive in Nassau at 5 p. m. Tour members will stay at the Fort Montagu Beach Hotel.

Sunday, Dec. 4. This day is free of planned activities.

Monday, Dec. 5. In the morning there will be driving in private cars around the island.

Tuesday, Dec. 6. Tour members will board a motor launch for Hog Island, where the bath house and facilities of Paradise Beach will be at their disposal.

Wednesday, Dec. 7. Physicians will have luncheon at the Jungle Club and spend the afternoon with members of the Bahamas Medical Association. Ladies can enjoy the hotel's buffet luncheon, which will be followed by a fashion show displaying Egyptian cottons, English linens, and native straw accessories. The new Montagu Roof Garden will be the setting in the evening for a cocktail party with entertainment. Dinner will be specially arranged around native dishes such as cocoanut-fried chicken, Bahamian conch chowder, and stuffed lobster Nassauvian.

Thursday, Dec. 8. This will be a day of leisure, as will be Friday, Dec. 9.

Saturday, Dec. 10. Alternate departures for Miami via BOAC's new Viscounts. Departure at 10:15 a. m., with arrival at Miami at 11:15 a. m., or a few hours later, with departure at 6:30 p. m. and arrival in Miami at 7:30 p. m.

TRAVELERS TO WORLD MEDICAL ASSOCIATION MEETING

The picture below shows Dr. and Mrs. Dwight H. Murray and Dr. and Mrs. F. J. L. Blasingame prior to their departure for Europe via Scandinavian Airlines. Dr. Murray is the newly elected President of the American Medical Association. Dr. Blasingame is the Vice-Chairman of the Board of Trustees of the A. M. A. They were en route to the World Medical Association meeting in Vienna, Austria, Sept. 20-26.

Left to right: Mrs. Dwight H. Murray, Dr. Murray, Mrs. F. J. L. Blasingame, and Dr. Blasingame.

PUBLIC RELATIONS

Those Difficult Patients

There is a daily parade of people through almost every physician's office. Some of these individuals by their actions and attitudes slow down or bring to a complete halt this orderly procession. These are the patients doctors label as "difficult"—the shoppers, the talkers, the belligerents, and occasionally, those who are dissatisfied. These individuals complicate the task of running an efficient medical office and present definite public relations problems as well. Some are touchy and easily annoyed; others are inclined to become dissatisfied with the doctor or their medical care quickly. It has been found by medical societies that many of the complaints about medicine and the medical profession today are being voiced by such problem patients.

Consequently, even though such patients are trying to the physician, they must be dealt with thoughtfully and with special consideration. What makes certain patients "difficult?" Almost all of them reflect anxiety about their conditions. Some are distrustful of the doctor and suspicious of any medical procedure. Others are unable to cope with trying situations in life and so they take refuge behind physical symptoms. Many are reacting in a negative fashion to their illness and to the position of authority of the physician they have been forced to seek.

Dr. Howard P. Rome of Rochester, Minn., says: "Obviously, the static approach to clinical medicine which treats all patients as though they were simply the noncontributing carriers of diseases or injuries will yield a high percentage of difficult patients. Everything depends upon how the physician responds to the patient's recital of worries, whether with pointed inquiries, a shrugging dismissal of a symptom, or an enigmatic blandness that leaves the patient in an even worse quandary." Dr. Rome believes every patient requires a different method of approach according to the individual's psychology. Certain techniques are involved in these varying approaches. Here are some suggestions from practicing physicians for dealing with difficult patients:

Shoppers.—Every physician—especially a man just setting up practice—is confronted from time to time with "shoppers." These patients move from doctor to doctor, searching for the words they want to hear. Sometimes these individuals are seeking a contradictory diagnosis, sometimes the lowest-priced medical care; sometimes they are not sick at all but are searching for a doctor who will say there is a physical basis for their mental ailments. Should a doctor criticize a diagnosis that another physician made previously, such patients are inclined to seek compensation for the earlier "mistake" or to complain loudly to the neighbors and friends, thus undermining public confidence in physicians. Shoppers should be firmly urged to return to their own doctors, unless they have actually terminated the earlier doctor-patient relationship. Physicians recommend in such cases complete histories be taken, and they warn against talking disparagingly against other physicians.

Talkers.—"Gabby" individuals run on forever if allowed to, taking up more than their share of the doctor's time and sabotaging the appointment schedule. Sometimes, in an early conversation with such persons, the doctor's receptionist can spot a "talker." In some offices, talkers' cards or case histories are marked with a symbol that alerts the physician. Other doctors have their assistants pointedly remind them when bringing in a talker that the next patient will arrive promptly o schedule. The physician must phrase his questions carefully when interviewing such patients, since the mor general his questions the longer the answers will be One doctor says that a firm interruption now and the to get the conversation back on the track can be use without the patient taking offense (talkers are used t being interrupted by others). Some doctors use a concealed buzzer to signal their assistant when it seems impossible to conclude a visit with a talker in a reasonabl length of time. The assistant then enters to say: "Docto I'm afraid you've run overtime. Your next patient ha arrived." Another effective way to cut short length time-consuming conversations with such patients is suggest they return for another appointment to discu their condition. Few patients want to pay for anoth visit just to talk.

Belligerents.—Some patients actually seem to delig in disobeying the doctor's instructions. No matter wh the psychological reasons for their rebellion, the phy cian should try to convince such patients that his orde have merit and are to the patient's best interest. He m have to state firmly: "I will no longer serve as yo physician if you don't follow my orders. I won't be sponsible for what happens if you do not cooperat Often, the doctor should put such a statement in t form of a letter to the patient to protect himself.

Dissatisfied Patients.—The physician whose dissat fied patient brings the grievance directly to him f discussion is fortunate. Generally, such persons co plain loudly to friends and neighbors about their grie ance, but the doctor hears about it only indirectly, if all. When a patient does complain, the physician m listen patiently, even if the complaint seems ridiculo or unjustified. What are the reasons for the complain Is misunderstanding the cause of the trouble? Or is t complaint justified? In many instances the doctor c settle the complaint to the patient's satisfaction after few minutes' discussion. When the patient cannot satisfied, the doctor should suggest the patient put h complaint in writing and submit it to the local medic society's mediation committee for hearing. Such co mittees convince patients that physicians sincerely a trying to settle grievances justly.

In most cases, problem patients can be turned in amiable, cooperative patients. Each difficult patient pr sents a challenge to a physician's dexterity in huma relations.

PRoblem Corner

No physician enjoys crawling out of bed during th night to answer an emergency call. He knows from actu experience that the majority of such calls are fals alarms. Yet—one out of 10 such calls may be a re emergency. Since no doctor has a crystal ball to help him differentiate over the telephone the real from the fancied emergencies, he takes a great risk in refusing any such call. The one emergency case that goes untended creates a tremendous public relations problem for the entire profession. Here's what happened in one midwestern city recently:

At 5:45 a. m. one Sunday recently a frantic father told a telephone operator his 5-year-old daughter was in convulsions and that he could not remember the telephone number or spelling of his doctor's name. The operator quickly traced the doctor and put through a call to him. His wife answered and berated the operator for calling the doctor so early. When the father was put on the line and explained that the inhalator squad had already been called to his home to revive the child, the wife finally allowed him to speak to the doctor. The physician agreed to accept the call. The doctor's wife then came back on the line and told the operator not to ring them for any more emergency calls, and the doctor reiterated the request in somewhat abusive terms.

Because of the telephone operator's persistence, tragedy was averted. The doctor admitted to the father he was glad the parents insisted on his coming at once, as the little girl was more seriously ill than he had imagined. The grateful mother later wrote a letter of appreciation to the telephone company praising the efforts of the operator in securing a doctor. The telephone company got good public relations out of the incident, but how much ill will was engendered by the attitude of the physician and his wife in this instance? The telephone company official who reported the incident stated in a letter that there were "too many such occurrences."

The medical profession has accepted the responsibility for providing emergency medical care. What can the profession do to assure that individual physicians do not shirk this responsibility? The physician's wife must understand the nature of this responsibility too, since she often can do irreparable harm to the public relations of the individual doctor. Public relations is more than just the responsibility of the physician—it is the responsibility of his wife, his family, and all those associated with him in his practice.

Encouraging Traffic Safety

Few persons are better qualified to point out to the public the terrible consequences of traffic accidents than physicians. By promoting traffic safety, physicians in a number of communities are rendering a real community service and incidentally netting better public relations. A Warrenton, Va., physician reports one effective traffic safety promotion accomplished in his town. "In our town when the highway department refused a stop light for a dangerous intersection, we sent a delegation of two doctors (one representing the local hospital) and an undertaker to explain how 'profitable' that intersection had been. The hospital and undertakers' bills were quite impressive. We got *two* stop lights—and at once."

In a similar move, physicians of the Schuyler County (N. Y.) Medical Society called attention of county officials to a dangerous curve near an intersection. The letter pointed out that one person had been killed and several injured at the spot. Action to abolish the curve was urged. The community newspaper used the society's letter as the basis for an editorial and further emphasized the need for action. Medical public relations need not be limited to medical affairs. The opinion of the medical society on any community situation often carries great weight. Voicing that opinion constructively often results in improved public relations for the profession.

MEDICINE AND THE LAW

MEDICO-LEGAL ASPECTS OF TISSUE HOMOTRANSPLANTATION

Allan D. Vestal, LL.B.
Rodman E. Taber, M.D.
and
W. J. Shoemaker, B.S., Iowa City

Reprinted with permission of the authors from the Detroit Law Review *(March 7).*—Ed.

Commencing with the transfusion of blood shortly before World War I, the concept of transferring tissue from one individual to another as a life-prolonging or lifesaving measure has acquired general acceptance by physicians and the public. Blood transfusion has progressed from initially hazardous, experimental procedure to one of common and every day usage in both large and small hospitals. The principles and techniques of transfusion are sufficiently well understood by the medical profession and lay public alike that no written authorization from the recipient is required for a transfusion.

During the past ten years the field of tissue transplantation has received increasing attention. Classical experimental work was carried out at the turn of this century [1] in connection with arterial transplantation. It was clearly shown to be a feasible procedure at that time but due to lack of advances in supportive facilities it was not carried over to human application. Following World War II, much of the original experimental work was repeated [2] and in 1948 [3] the first successful series of arterial homotransplantations was carried out in man. The rapid development of supportive facilities at this time in the fields of anesthesiology, applied physiology, and the antibiotics made these procedures safe to perform in the clinical field. Further advances in methods of tissue storage [4] have extended the usefulness of vessel transplantation so that at the present time this procedure is being carried out in many of the larger hospitals in this and foreign countries. The surgical treatment of obstruction or abnormal dilation of major arteries due to arteriosclerosis or "hardening of the arteries" is accounting for its most frequent use. Arterial transplantation makes it possible for the surgeon to excise the diseased vessel and substitute a healthy one in its place. These conditions have become of increasing importance due to a steady rise in the proportion of aged people within our population. Arterial homotrans-

plants were successfully utilized in treating war injuries during the Korean conflict.

The transplantation of skin from a donor individual to a severely burned patient, or skin homografting, accounts for a modest number but frequently lifesaving type of skin grafting procedure. In this surgical procedure, the donor skin survives for a few weeks rather than permanently, but during this period the patient may be carried through a critical phase of his illness. In the very severely burned patient, the remaining unburned areas may not be sufficient to permit the use of his own skin for grafts. In this situation, the skin homotransplant constitutes a lifesaving application. The majority of skin transplants are carried out from one part of the individual to another part and therefore do not involve a donor and recipient. It is possible and has recently proven successful [5] to use skin removed from a deceased person for the former type of skin transplant. This tissue source would mean that parents and relatives of patients requiring this type of procedure would be spared the pain and disability of serving as donors. The need for transplanting skin from one individual to another arises most frequently in the case of severely burned children. Another need, and one which it is hoped will remain theoretical for some time, is in dealing with the extensive burns incident to an atom bomb conflict. Both civilian and military application would be involved.

The transplantation to a patient of bone tissue removed from another individual is a practical surgical procedure. In this application of tissue transplantation, the donor tissue is frequently obtained from patients who require chest surgery. It is commonly necessary to remove a portion of a rib from these patients in order to gain access to the interior of the chest. This type of donor tissue is therefore usually available without subjecting an individual to a separate surgical procedure for the purpose of obtaining the transplant material. Occasionally, bone homotransplants removed from the recently deceased have been used.

Based on sound experimental work,[6] the transplantation of portions of the cornea of the eye has become a frequently practiced operation in hospital centers of the United States and Great Britain. Many children and adults have had their sight restored through the use of this form of tissue transplantation. Many more are awaiting the procurement of sufficient donor tissue so that they may receive the benefits of this type of surgery.

The surgical procedures of vessel, skin, bone and cornea transplantation have each weathered a long period of experimental development. Considerable fundamental information remains to be learned about these and other types of tissue transplantation. The acquisition of this knowledge will in all likelihood expand the scope of their application.

The full utilization of techniques, those known now and those that may be discovered in the area of tissue transplantation, will certainly require greater amounts of donor tissue than have been available in the past. In the nature of things, medical personnel working in this field look generally to those who have recently died as the most frequent source. At the present time there is no routinized, common procedure by which such tissue is obtained, rather various individuals are using diverse methods. Some individuals working in this field have obtained written consent of the nearest of kin as well as routine postmortem authorization before removing tissue for transplantation purposes at the time of necropsy. Others have required only the necropsy authorization.[7]

In the early days of experimentation, such haphazard procedures were sufficient and provided an adequate supply of tissue with little difficulty. With the rapid increase in application of these operative techniques, the demand has in many localities far outdistanced the available supply. As a result, physicians performing these operative procedures have become interested in maximizing the source of such tissue while at the same time minimizing the possibility of legal difficulties.

LEGAL BACKGROUND

Originally in England the ecclesiastical courts exercised jurisdiction over matters concerning dead bodies.[8] Recognizing such jurisdiction, Lord Coke said such matters were not under the cognizance of common law courts.[9] From this there arose the concept that there were no property rights in a dead body.[10] It was not until the latter part of the 17th century that the common law began to take jurisdiction of religious offenses and by this time the concept was accepted that there were no property rights in dead bodies.[11] Since the time of Lord Coke the cases have held uniformly that there is no right of ownership in a commercial sense in a dead body.[12] It has been pointed out that the incidents of ownership, such as the rights to dispose of the property, to abandon it, to exclusive possession, to destroy, alter or improve it are not present.[13]

Even the courts which flatly state there is no property in a dead body do agree that there is a right of possession of the body for purposes of burial.[14] Other courts take the view that the right to possession and disposal is in the nature of a "sacred trust."[15] Regardless of whether this right is a quasi-property interest in the body, or a property interest, or something else, the courts have held that this right belongs to the surviving spouse, children, and then next of kin in that order.[16] In the growing law in this area the common law courts developed the idea that any exhibition of a dead body, even for scientific purposes, was a common law offense.[17] It was held in *Regina v. Francis Scott* [18] that a dead body could not be detained as security for the payment of a debt.

The law with respect to human bodies is ever changing. As Mr. P. E. Jackson points out in the introduction to his treatise on "The Law of Cadavers," ". . . when we go to the common law for bases for rules of law respecting dead bodies and their disposition, we find little or nothing of value. . . . When we look to our own substantive law for precedents, we find that our courts . . . in the determination of these questions . . . were not concerned with property rights, but were dealing with sentimental matters affecting domestic relations." [19] As the law in the various jurisdictions today indicates, the rules concerning human bodies are not so much concerned with property rights as they are with ". . . considerations of love, reverence, public health, comfort, and convenience. . . . In the formulation of these rules, it became possible to give heed to modern conceptions of human value and rights and to deny the force of mechanically created postulates of the common law."[20]

Rules respecting rights and remedies in dead bodies usually spring from respect for natural feelings and emotions.[21] One court stated that all questions which arise out of and which regulate custody and disposal of dead bodies depend not upon the principles which regulate possession and ownership of property but upon considerations arising out of domestic relations and ties of blood.[22]

The general policy concerning dead bodies can be articulated as follows: 1. Rights in a dead body exist ordinarily only for purposes of disposal and a dead body is not property in the ordinary commercial sense.[23] 2. The person who has the privilege of exercising the right [24] of disposal or the person who is charged with the duty [25] of disposal is entitled to the possession of the body for that purpose.[26] 3. The person who has the right of possession is entitled to receive the cadaver in the same condition as it was in when death occurred.[27]

There are numerous exceptions to the elicited general rules and a large number of statutes with respect to dead bodies deal specifically with these exceptions which fall into several well-defined groups.

First the sanctity or immunity of a cadaver must give way before the general interest of the public when an autopsy is required for the protection of health or the discovery of crime.[28] In such a case, the welfare of society demands that the state or its authorized representative be permitted to conduct an examination by dissection without reference to the wishes of the relatives of the decedent. No action can be maintained against a coroner or against the examining physicians for the ordering or performing of an autopsy or postmortem examination where the circumstances are such as to render the examination reasonably necessary and proper in the exercise of the duties of such coroner and medical examiners if the work is done in a decent manner and without wantonly disfiguring the body.[29] The question of whether the autopsy services of the coroner are necessary in each case of death involving suspicious circumstances is one largely within the sound discretion of the coroner.[30] The right of relatives to the possession of the body for purposes of burial is subordinate to such a right.[31] It has even been held that where a physician, unable to determine the cause of death without an autopsy, proceeds, without the consent of the next of kin, to make an examination in a decent and proper manner for the purpose of making a death certificate, the courts impose no liability on him.[32]

The sanctity of the cadaver has given way to the public interest in the correctness of an adjudication between parties to civil litigation. This interest in the outcome of actions between parties has resulted in the legal approval of a provision in insurance contracts which authorizes an autopsy to ascertain the cause of death.[33] Even without such a contractual provision, a court may order an autopsy to establish certain facts in civil litigation.[34]

The public interest in the prosecution of crime and the vindication of legal rights has led also to the passage of legislation which provides for the disinterment of dead bodies.[35] Although the courts may be reluctant to exercise discretion granted under such legislation,[36] the basic policy of such laws seems quite clear. In such legislation, the justification may not be in terms of criminal responsibility, but rather civil liability.[37]

The interest of the public in the promotion of medical education and scientific progress has also led to some relaxation in the usual immunity attached to dead bodies. Because of the very nature of the science of medicine, a number of cadavers are needed for research and education. To meet this need, a number of states have passed legislation. A typical statute provides that the ". . . director or person in charge of any hospital, institution, morgue or other place for bodies of deceased persons not interred or otherwise finally disposed of, and every funeral director, undertaker or other person having in his lawful possession, any body of a deceased person for keeping or burial, shall deliver every body of a deceased person in his possession . . . not placed therein by any person, agency or organization for keeping, burial or other lawful disposition, to: (1) any medical college, school or institute registered by the regents . . . (2) any university within the state authorized by law to confer degrees of doctor of medicine or doctor of surgery; . . ." [38] Furthermore, permission is given to use the body for the purposes of medical, anatomical and surgical science and study.[39]

Thus, public policy has seen the need of medical-scientific uses of dead bodies and has provided a legal means for obtaining dead bodies to help save the lives of others.

The same interest in medicine and scientific progress behind the unclaimed cadaver laws would seem to result in the approval legally of the concept that an individual can give consent to the performance of an autopsy in the interest of science or even that an individual can give his body for scientific investigation.[40]

These exceptions to the general rules, developed because of the natural hesitancy to cut or dissect a human body, suggest the direction in which public feeling has developed toward dead bodies. Whereas there is much feeling of reverence and sacredness concerning cadavers, the knowledge that science and medicine need to utilize dead bodies to save the lives of other humans and to promote socially acceptable ends has resulted in great breaks in the protective wall surrounding the dead body. When society's needs have required it, the sanctity and immunity of dead bodies have given way.[41]

PRESENT STATE OF THE LAW

The use of tissues for transplantation, of course, has repercussions in a vast number of fields.[42] In law there are at least two areas that are concerned. First, the persons involved may find that they are subject to criminal prosecution for their part in the operation;[43] additionally, they may find that they are subject to a civil action for damages because of the act of transplantation. In order to limit the scope of the coverage, this article is limited to the problem of civil liability of a doctor [44] for the taking [45] of tissue from a body. Other facets of the problem will not be discussed herein.[46]

The medical profession is faced with two quite dissimilar legal problems in obtaining tissue for therapeutic use. One is that of getting tissue, for example, corneal matter, from a living donor. The other is getting tissue from a dead body. Although the medical profession may consider the problems as similar, the legal considerations are quite different.

It seems quite probable that a living individual, even in the absence of statutory authority, can give a part of his body.[47] That there is very little authority on the matter is readily understandable since there is a serious question whether anyone except the willing donor has any interest at all in the matter. For example, when a person donates a pint of blood, it seems apparent that another cannot urge that he has been injured. Some jurisdictions, it is true, have passed special legislation giving to an individual the right to determine what shall be done with a part of his body which has been separated from the body.[48] However, this sort of legislation would seem to be merely a restatement of the existing law on the matter.

Living donors would seem to be a rather limited source for tissue to be used for therapeutic purposes. Some elements of the body are readily replaced, such as blood, so that living donors are an excellent source. But this is not true of most of the tissue to be used as homografts. Occasionally a living donor is separated from part of his body through accident or required surgery, and then there is a possibility that such tissue from a living source could be used. In addition some donated tissue can be obtained from living individuals. For example, corneal tissue given by a parent for a blind child. But it seems apparent that if any great amount of tissue is to become available for homografts it must come from the bodies of deceased individuals.

Turning then to cadavers as a possible source, one concludes that there are several legal approaches to the matter. First, as mentioned above, a number of jurisdictions have passed legislation designed to furnish cadavers to medical schools and other such institutions.[49] One statute, which is more or less typical, provides: The body of every person dying in a public asylum, hospital, county home, penitentiary, or reformatory in this state, and which is suitable for scientific purposes, shall be delivered to the medical college of the state university, or some osteopathic or chiropractic college or school located in this state, which has been approved under the law regulating the practice of osteopathy or chiropractic; but no such body shall be delivered to any such college or school if the deceased person expressed a desire during his last illness that his body should be buried or cremated, nor if such is the desire of his relatives or friends. Such bodies shall be equitably distributed among said colleges and schools in accordance with such rules as may be adopted by the state department of health, but the number so distributed shall be in proportion to the number of students matriculated at each college or school. The expense of transporting said bodies to such college or school shall be paid by the college or school receiving the same.[50]

On the face, such statute would seem to offer a possible source for tissue for therapeutic purposes. In fact, this is not true because of at least two reasons. First, in many states where there are no large cities, such statutes do not have any real application because there are very few unclaimed bodies, and the medical schools are forced to get cadavers for educational purposes through commercial channels. Moreover, such cadavers are so treated as to be entirely unsuited for homografts. Secondly, in this type of legislation there is usually a provision such as the following: When any dead body which has been delivered under this chapter for scientific purposes is subsequently claimed by any relative or friend, it shall be at once surrendered to such relative or friend for burial without public expense; and all bodies received under this chapter shall be held for a period of sixty days before being used.[51] Since the tissue, under present medical practice, must be obtained and processed within a very short period of time, such a statutory provision above means that tissue from such cadavers is not available for therapeutic use.[52] Also, although it would not seem to pose a real problem, such statutes were not drafted with therapeutic use in mind, and a strict interpretation of the statute might seem to exclude the use of tissue for transplanting.[53] However, the better view would seem to be that, if such tissue could be used, that its use for therapeutic purposes would fall within the scope of such legislation.[54]

Another possible legal approach to the question of getting tissue from deceased individuals is that of getting permission to take such tissue. This could be either ante-mortem permission from the prospective donor or post-mortem permission from those who have the right of possession of the body.

First, ante-mortem permission from the prospective donor. The legal background in this area offers no definitive answer to the problem of whether ante-mortem donation of tissue for therapeutic use is legally effective. However, the growth and development in the area do suggest the probable present state of the law. Dicta in a number of early cases would suggest that such ante-mortem consent would be good.[55] Many of these cases arose in connection with the right of an individual to control the place of interment of his body. Almost without exception, courts have held that an individual has the right to control the place of interment.[56] The limited authority to the contrary seems to be readily understandable when the facts are considered,[57] and the precedent value of the authority may be questionable.[58] The same control of an individual over the disposition of his body was recognized in the matter of cremation. An individual can direct that his body be cremated, and such direction will be enforced.[59] A third group of cases in the area involved the right of an individual to contract with an insurance company for the performance of an autopsy upon death, at the discretion of the company.[60] Although such contracts have been interpreted restrictively,[61] the basic right of an individual to contract concerning his body after death has consistently been upheld. Under an insurance policy which provides that the company shall have the right to have an autopsy performed, a court may exercise equitable jurisdiction, when demand for an autopsy is refused, to entertain a bill for discovery and to appoint a receiver to assume responsibility for the organs of the deceased pending examination to determine the cause of death. Under the contract the company has a right to conduct an examination of the organs superior to any right of any member of the family of the deceased.[62] In addition, a number of states have by statute specifically provided that an individual can provide that his body be disposed of as he designates, for example, for scientific purposes.[63] Although there is room for argument, it seems reasonable to assert that such legislation merely restates the existing law.[64] It may be valuable for clarification and to eliminate the possibility of doubt, but it seems probable that such legislation does not add to the law.[65]

It would seem to be fair to conclude that a person at the present time in the United States probably has the right to control the disposition of his body after death as long as no public policy is contravened,[66] and it would seem to follow that an individual in his lifetime can give permission for the taking of tissue from his body after death. In some areas this may be a feasible long-range approach to the problem. Through public education, it may be possible to sell the public generally on the idea that the giving of such ante-mortem permission is desirable. However, at the present time, this is not a very productive source of tissue. The question of donation is not a pressing one until the individual is in a hospital, and then there is an understandable reluctance to raise the question.[67] A request for permission to use tissue after death would be a most shocking experience to a patient. And in many cases there might be a very serious question about the legal capacity of the patient to give such permission.

Secondly, there is a possibility that post-mortem permission might be obtained from those entitled to the body. Again we find very little authority but it seems that were such permission obtained, any serious legal difficulties would be avoided. If the relative or relatives with the right to possess the body [68] should give their consent, it would seem that no legal difficulties could arise since no other person would have the legal standing to raise the question,[69] and the person with the right legally to assert a cause of action apparently would be barred or estopped by the authorization. It should be noted that there is generally no statutory authorization for such permission.[70] The closest statutes are those that authorize an "autopsy of post-mortem examination" when post-mortem permission is given by one entitled to the body.[71] It is possible that such a statute might be liberally construed to include the removal of tissue for therapeutic purposes. But it does seem that statutory authority for removal of tissue is not required to avoid civil liability if permission of those legally interested is obtained.

The realistic approach to the matter at the present time must be based on one very simple fact. The one great, readily available source of tissue at the present time is the steady flow of bodies on which autopsies are performed. There are many autopsies performed under the various statutory authorizations. For example, Iowa provides for the performance of autopsies when desired by a coroner in examining into deaths ". . . of such persons only as are supposed to have died by unlawful means, . . ." [72] and for autopsies in certain other special situations.[73] In addition, there is a statutory provision that an autopsy or post-mortem examination may be performed upon the body of a deceased person by a physician or surgeon whenever the written consent thereto has been obtained in any of the following manners: 1. By written authorization signed by the deceased during the lifetime. 2. By written consent of any party whom the deceased during his lifetime designated by written instrument to take charge of his body for burial. 3. By consent of decedent's surviving spouse. 4. If the surviving spouse is incompetent, unavailable, or does not claim the body for burial, or if there be no surviving spouse, by consent of any adult child, parent, brother or sister of the decedent. The consent of any one of such persons shall be sufficient provided that such autopsy shall not be performed under a consent given by one of such persons if, before such autopsy is performed, any of said others shall object in writing to the physician or surgeon by whom the autopsy is to be performed. 5. If none of the above persons is available to claim the body, then by consent of any other relative or friend who assumes custody of the body for burial.[74] Such ante-mortem [75] consent or post-mortem [76] consent for an autopsy probably is effective even in the absence of statute.[77]

Under these and similar provisions,[78] there are a great number of bodies that are opened and tissue examined. Various parts are removed for scientific reasons, some parts are not replaced, the body is returned essentially to its original external appearance and turned over to the proper individual for burial. It seems to be a practice—of some widespread acceptance—to remove and keep, for scientific purposes, tissue from bodies being subjected to autopsy. As far as the authors have been able to ascertain, no litigation has arisen over the taking of tissue for therapeutic purposes. In *Palmquist* v. *Standard Accident Insurance Company*,[79] the deceased husband of the plaintiff had an insurance policy with the defendant. The policy provided that the insurer had the right to make an autopsy in case of death. The insurance company, under the authority contained in the policy and with the permission of the plaintiff performed an autopsy. The physicians representing the insurer removed some organs for pathological examination. The organs were retained for "some months." A demand was made for their return, but the company's doctors retained possession, and continued in possession until the time of trial. No reason was given for the continued possession of the organs, and the jury returned a verdict in favor of the plaintiff for $1,500.

In *Palenzke* v. *Bruning* [80] an autopsy was performed under the authority of a coroner. The court stated: Unless sufficient reason existed for an autopsy [the plaintiff] was entitled to the body unmutilated. If such reason did exist, he was, nevertheless, entitled to the whole body, even though necessarily disfigured, unless it proved necessary to remove and preserve some particular organ for further examination, as to whether a crime had been committed, or for evidence. But no one—coroner, nor doctor, nor undertaker—had the right to remove parts of the body and, without the parents' consent, throw them into a privy vault. Such conduct violates every instinct of propriety, and could not fail to outrage the feelings of the kindred of the deceased. For such violation of the [plaintiff's] rights an action for damages can, we think, be maintained.[81] The court held the demurrer should have been overruled and that the plaintiff stated a cause of action.

In *Hassard* v. *Lehane* [82] the court was faced with a case involving an illegal dissecting of a body by a coroner's physician. The doctor, without authority, performed an autopsy ". . . removed the heart and spleen, and cut them into many pieces, and had them preserved in alcohol in a jar in his office . . . the only explanation offered by the defendant was that the decedent had a greatly enlarged spleen, and was an interesting case." [83] The court held that nonsuit at the end of plantiff's case should not have been granted. The court noted that ". . . even if the autopsy had been authorized by the coroner, that did not, on the facts here presented, justify the removal and detention of any of the organs of the decedent." [84]

These cases suggest that an individual may be forced to answer in a law suit which alleges that, after an autopsy, parts have not been returned when no reason is given for the failure to return such tissue or when the reason given is considered to be insufficient. The cases do not definitely decide the legality of the removal of tissue for therapeutic purposes during an autopsy. These cases do suggest that when an autopsy is performed the purpose to be served may be of great legal importance. Where the investigation of crime is involved, the autopsy may take place under certain limitations;[85] when the matter at hand is the cause of death and the application of an insurance policy certain other restrictions may operate. When the autopsy is being performed under a general grant of consent in the interest of science, other conditions may be operative. In other words, the autopsy must be conducted within the terms of the authority given.[86] An unnecessary violation will give rise to liability. However, a reasonable construction must be given to such authority.

When an autopsy is performed, authorized either by statutes or by consent given by the person entitled to the body, there is a logical implication that there is given to the doctors ". . . permission . . . to conduct such examination in the approved and usual manner practiced by their profession."[87] As one authority has stated: It has always been customary to remove from a body during a post-mortem organs and specimens for the purposes of pathological and histological examination and preservation and demonstration specimens. There is no statutory bar to such actions, and it does not fall within the definition of the desecration of a body, if it is done bona fide and decently, in accordance with universally accepted medical practice. If consent is given to the post-mortem, it must be taken to include consent for this purpose, which is considered to be an integral part of post-mortem procedure.[88]

The bodies on which autopsies are performed then would seem to be an excellent source of tissue for therapeutic purposes. Persons performing such autopsies might well remove tissue for storage in "banks," since ". . . there . . . does not seem to be any legal barrier to this being done if the operator chooses to do so voluntarily, provided that there is no visible mutilation of the body other than that inseparable from the usual requirement of post-mortem techniques." [89]

A doctor engaged in homotransplantation can probably obtain tissue in sufficient amounts using post-mortem authorization of the next of kin and still obtain a reasonable degree of protection from civil liability. This would involve getting from the next of kin[90] a statement of authorization or request for dissection.[91] Such writing could be so drafted as to include, without any question, the right to take tissue for therapeutic use.[92] Legally this would then involve the taking of tissue by postmortem consent, as well as the performing of autopsy discussed immediately above. The obtaining of tissue in this manner, buttressed then by both specific postmortem consent and the precedent to be found in the accepted practice of pathologists, would seem to be proper beyond any reasonable doubt, and would not subject the participating doctor to legal liability.

PROGNOSIS

Unless some substitute is found for human tissue now being used in homotransplantations there is every reason to believe that there will be an ever growing demand for such tissue. The law as it now stands should not impede the progressively greater use of homografts. In fact, the reasonable utilization of the available legal devices should produce sufficient tissue. Immediately, through the greater use of consent by the surviving kin, an expanded supply can be obtained. Then through education the device of the ante mortem consent of the donor himself can be used to increase the supply of tissue for therapeutic purposes. The legal devices are available; the next step is the cooperation between the medical and legal profession to utilize these devices.

Since this article was written, the Fifty-sixth General Assembly of the state of Iowa has passed and the governor has signed into law a comprehensive act, House File 167 (as amended), dealing with cadavers and their use by the medical profession. One provision reads as follows: Every inhabitant of this state of the age of twenty-one years or more and of sound mind may, by his will or by a written instrument executed in the same manner as a deed, arrange for or prescribe for the disposition to be made, after death, of his body or any organ, member of part thereof, provided the same is for the purpose of scientific use as provided in this chapter, or for other advancement of medical science, or for the replacement or rehabilitation of diseased of worn out parts or organs of other humans. The person or persons having the right to a body for burial may likewise consent to such use of the body or parts thereof. And such disposition of his own body may be revoked by the testator or grantor at any time prior to his death by the execution of a written instrument in the same manner as the original grant. Such legislation is valuable in clarifying the legal rights and obligations involved.

MEDICAL NEWS

CALIFORNIA

Symposium on Heart Disease.—The 26th annual Postgraduate Symposium on Heart Disease, Oct. 5-7, at the St. Francis Hotel, San Francisco, will have as guest speakers Drs. D. Evan Bedford, London, England; Franklin D. Johnston, Ann Arbor, Mich.; Elliot V. Newman, Nashville, Tenn.; Edith L. Potter, Chicago; and Myron Prinzmetal, Los Angeles. Cooperating with the San Francisco Heart Association in this program will be the county heart associations of Alameda, Monterey, San Mateo, and Santa Clara. Topics for discussion will be: Electrocardiography and Vectorcardiography; Congenital Heart Disease; Pathology and Diagnosis; Coronary Artery Disease; and Therapy. Dr. Bedford, the speaker at a dinner meeting Thursday evening, will present "New Lamps for Old in Cardiology."

Escape from Aircraft.—A symposium, "Escape from High Performance Aircraft," will be held in Los Angeles Oct. 7, under the auspices of the Aero-Medical Engineering Association. The all-day symposium and the dinner and evening round-table discussions will be presented at the Institute of Aeronautical Sciences Building, 7660 Beverly Blvd., under the cosponsorship of the Institute of Aeronautical Sciences, Los Angeles section, and the Institute of Transportation and Traffic Engineering of the University of California. Nationally known authorities in the field will discuss methods of escape, designing for protection, personal equipment for protection, and the physics, physiology, and psychology involved. Case histories of actual escapes under emergency conditions will be presented.

Medical Lecture Series.—The annual medical lecture series sponsored by University Extension and the University of California Medical School in Los Angeles will be presented on Mondays, 7:30-9:30 p. m., Oct. 3-Dec. 19, in the first floor lecture hall (room 13-105) of the medical center, with Dr. David H. Solomon as chairman. Lecturers will discuss Management of Peptic Ulcer, Chronic Liver Disease, Indications and Results of Common Cardiac Surgical Procedures, and the Current Status of Tuberculosis and Systemic Fungus Infections. Applications for admission to the series (fee, $50) should be addressed to Dr. Thomas H. Sternberg, Assistant Dean for Postgraduate Medical Education, Medical Extension, University Extension, University of California, Los Angeles 24 (BRadshaw 28911-extension 202).

ILLINOIS

Psychiatric Lectures.—The sixth annual North Shore Health Resort lectures on psychiatric problems will open Oct. 5 at 8 p. m. at the hospital (225 Sheridan Rd., Winnetka) with "Management of Psychiatric Emergencies" by Dr. Karl M. Bowman, professor of psychiatry, University of California Medical School, San Francisco. The Commission on Education of the American Academy of General Practice has approved these lectures for informal credit. The J. B. Lippincott Company of Philadelphia will publish the entire series as a book. All royalties that will accrue have been assigned to the American Psychiatric Association, of which Dr. Bowman is a past-president. All physicians are cordially invited to these lectures.

Chicago

Monthly Cardiac Conference.—The monthly clinicopathological cardiac conference of Cook County Hospital will be held Oct. 7 from 11 a. m. to 12 noon at an open meeting in the Children's Amphitheater, 700 S. Wood St. "Recent Advances in the Diagnosis of Congenital Malformations of the Heart" will be presented by the guest speaker, Dr. Alexander S. Nadas, the Children's Medical Center, Boston.

Annual Bevan Lecture.—Dr. Owen H. Wangensteen, professor of surgery, University of Minnesota Medical School, Minneapolis, will deliver the 27th annual Arthur Dean Bevan Lecture of the Chicago Surgical Society at the Knickerbocker Hotel, 163 E. Walton St., at 8 p. m. Oct. 7. The subject of his address will be "Current Accomplishments in Cancer of the Alimentary Tract with Special Reference to the Stomach and Colon." The profession is cordially invited to attend the lecture.

KANSAS

Lecture on Hospital Explosion Hazards.—The Sedgwick County Medical Society will have as guest speaker Oct. 4 Dr. George J. Thomas, director, department of anesthesiology, St. Francis and Medical Center Hospitals, Pittsburgh, who will present a lecture and demonstration concerning "Fire and Explosions Hazards in Hospitals and Their Control." Dr. Thomas is chairman, section on anesthesiology, University of Pittsburgh School of Medicine. Since 1938 he has been active in research on the prevention of fires and explosions with flammable anesthetic agents and has worked in close cooperation with the explosives division of the Bureau of Mines in Pittsburgh. Members of component medical societies of the Kansas Medical Society and Veterans Administration and armed services personnel are invited to attend the meeting. Dinner reservations may be secured by calling MU. 3-7557 or writing Sedgwick County Medical Society, 1102 S. Hillside, Wichita 17.

MASSACHUSETTS

Ballard Memorial Fund.—To honor the late James F. Ballard, who had been affiliated with the Boston Medical Library for almost 63 years and had served as its director for 28 years, one of the fellows of the library has offered to start a James F. Ballard Memorial Fund with a contribution of $5,000, contingent on significant interest in the memorial fund by other friends of Mr. Ballard and the Boston Medical Library. The income from the fund will be used primarily to establish a pension plan for the personnel of the library. Friends wishing to contribute may send checks, made payable to the Boston Medical Library, 8 Fenway, Boston 15.

MINNESOTA

Dr. Sogge Honored.—June 26 was Dr. Sogge Day at Windom, with residents of the area and professional colleagues gathering to pay tribute to Dr. Ludwig L. Sogge for his 50 years of service in medicine. Keynote speaker on the program was Dr. Frederic J. Kottke, former resident of Windom and now head of the department of physiotherapy at the University of Minnesota, Minneapolis. The day's activities included a dinner for medical men of the area, followed by an afternoon program of speeches and entertainment in the high school auditorium.

MONTANA

Society News.—The Montana-Wyoming chapter of the American College of Physicians will hold a regional meeting in Billings Oct. 7-8, 1955. All physicians in Montana, Wyoming, and the adjoining states are invited to attend. Dr. Harold W. Gregg, Butte, college governor for Montana and Wyoming, will be toastmaster at a banquet at the Northern Hotel, Friday, when the guest speakers will be Dr. George F. Strong, Vancouver, B. C., Canada, president of the college, and Mr. Edward R. Loveland, Philadelphia, executive secretary.

NEW YORK

Emotionally Disturbed Children.—The Astor Home, Rhinebeck, a residential center for research and treatment for emotionally disturbed children, will hold its first annual Conference on Child Treatment Oct. 10. Participants will include Drs. Frank J. O'Brien, Brooklyn, N. Y.; Leo H. Bartemeier, Baltimore; Harvey J. Tompkins, Washington, D. C.; Ralph D. Rabinovitch, Ann Arbor, Mich.; and Earl A. Loomis Jr., Pittsburgh.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

University News.—Frieda S. Robbins, Ph.D., Rochester, has retired as associate in pathology at the University of Rochester School of Medicine and Dentistry after 32 years' service.——Dr. Robert P. Whalen, medical administrator in the Albany County Welfare Department, has been appointed instructor in public health at the Albany Medical College of Union University, and Dr. Franklyn B. Amos has been promoted from assistant professor to associate professor of public health.——Dr. Brian MacMahon, lecturer in social medicine, University of Birmingham, England, has been appointed associate professor of environmental medicine and community health at the State University of New York College of Medicine at New York City, Brooklyn, where he served as visiting lecturer during 1953 and 1954. At that time he conducted an epidemiological investigation into the incidence of leukemia and related disorders in Brooklyn over the past decade.

New York City

Dr. Lyall Named Professor of Clinical Surgery.—Dr. David Lyall has been promoted from associate professor to professor of clinical surgery at Post-Graduate Medical School of New York University-Bellevue Medical Center. Dr. Lyall also succeeds Dr. Herbert Willy Meyer, who resigned July 1 as director of the center's University Hospital Tumor Service and of the fourth surgical division of Bellevue Hospital. Dr. Lyall joined the staff in 1941 as instructor in surgery, when the school was the former New York Post-Graduate Medical School and Hospital. In 1947 he became instructor in surgery at Cornell University and returned to the New York Post-Graduate Medical School in 1948 when the school and hospital became a part of New York University-Bellevue Medical Center.

Elder Craftsmen Shop.—The Welfare and Health Council of New York City announces that it will open a nonprofit Elder Craftsmen Shop this fall, where citizens, aged 60 and over, will display and sell wood carvings, ship models, jewelry, leathercraft, and other articles made with their own hands. Mr. J. Donald Kingsley, executive director of the council, states that "The annual Hobby Show for Older Persons, which the council has sponsored for the past nine years, has encouraged thousands of men and women to use old skills and develop new ones. The Elder Craftsmen Shop will provide an important step to help them sell their articles in fair competition with other merchandise, to supplement their pensions and low fixed allowances and thus achieve some degree of self-support." A campaign will be conducted to secure funds to underwrite the shop initially. Temporary headquarters will be at the council offices, 44 E. 23rd St. Contributing memberships available include annual member, $10; sustaining member, $25; donor, $50; benefactor, $100; and founder, $1,000.

PENNSYLVANIA

Surgical Society Presents Award.—The first annual award of the Pittsburgh Surgical Society was presented at the recent annual meeting to Dr. Charles William Mayo, professor of surgery, Mayo Foundation, Rochester, Minn. After receiving the award, a plaque, Dr. Mayo addressed the members of the society and their guests on "Carcinoma of the Colon and Rectum with Special Reference to Precursory Lesions."

Philadelphia

Meeting on Care of the Cardiac Child.—The second annual Institute for the Care of the Cardiac Child will be held Oct. 5 at the Children's Heart Hospital, Conshohocken Avenue. Panel discussions (10 a. m.-12 noon) will consider congenital heart disease, active rheumatic fever, and chronic rheumatic heart disease. The discussions will be resumed after a buffet luncheon in the hospital dining room, 12:30 p. m., at which the speaker will be Mr. Thomas D. McBride, vice-chancellor, Philadelphia Bar Association.

Society News.—Newly elected officers of the Philadelphia Roentgen Ray Society include: Dr. D. Alan Sampson, president; Dr. Edwin L. Lame, vice-president; Dr. Herbert M. Stauffer, secretary; and Dr. Randal A. Boyer, treasurer.——The Hawthorne Surgical Society, sponsored and organized by the 1945-46 class of the Graduate School of Medicine of the University of Pennsylvania, will hold its second annual dinner meeting in Chicago during the annual meeting of the American College of Surgeons Nov. 2. The cost will be $8 per person; $13 per couple. For reservations, write to the secretary-treasurer, Dr. Julian A. Sterling, 1351 W. Tabor Rd., Philadelphia 41. Membership in the society is open to those members of the Graduate School of Medicine who are fellows of the American College of Surgeons or diplomates of the American Board of Surgery.——Dr. Edward L. Bortz will serve as moderator Oct. 3, 8:30 p. m., for "Our Aging Population," a program for the public, presented without charge by the College of Physicians of Philadelphia, 19 S. 22nd St. On Oct. 10 the topic for the public program will be "Homosexuality and Sexual Deviants" and the moderator Dr. Calvin S. Drayer.

SOUTH CAROLINA

Medical Day.—Greenville Medical Day, Oct. 4, will be observed at the Greenville General Hospital. After discussion of recent advances in pediatrics by Dr. J. Earle Furman and in medicine by Dr. Hugh P. Smith Sr., both of Greenville, "Radioisotopes" will be considered by Dr. Robert Robbins, Temple University School of Medicine, Philadelphia; "Recent Advances in Obstetrics" by Dr. Robert A. Ross, university hospital of North Carolina School of Medicine, Chapel Hill; and "Recent Advances in Surgery" by Dr. W. Emory Burnett, Temple University School of Medicine, Philadelphia. After luncheon "Chemotherapy and Radiotherapy of Cancer" will be discussed by Dr. Robbins; "Surgical Treatment of Bowel Cancer" by Dr. Burnett; and "Surgical Treatment of Gynecologic Cancer" by Dr. Ross. A social hour and dinner will precede the presentation of "Cancer of the Breast" by Dr. J. Elliott Scarborough Jr., director of the Winship Clinic, Emory University, Ga., and of the Steiner Clinic, Grady Memorial Hospital, Altanta, Ga.

TENNESSEE

Medical Assembly at Chattanooga.—The Tennessee Valley Medical Assembly will convene at Read House, Chattanooga, Oct. 3-4, under the sponsorship of the Chattanooga and Hamilton County Medical Society. Dr. Elmer Hess, Erie, Pa., President of the American Medical Association, will discuss "Management of Ureteral Calculi" Tuesday. Other out-of-state speakers and their first presentations include:

Philip Thorek, Chicago, Intestinal Obstruction.
Edgar Hull, New Orleans, Emergency Use of Corticoids and Corticotropins.
George T. Pack, New York, Carcinoma of the Breast.
Robert B. Greenblatt, Augusta, Ga., Use and Abuse of Endocrines in General Practice.
Arthur C. Curtis, Ann Arbor, Mich., Cutaneous Manifestations of Systemic Disease.
Brian B. Blades, Washington, D. C., Traumatic Injuries of the Chest.
Harry E. Bacon, Philadelphia, Anal and Rectal Lesions and Their Treatment.
Waldo E. Nelson, Philadelphia, Pediatric Care by the General Practitioner.
Alton Ochsner, New Orleans, Cancer of the Lung.
Thomas J. Dry, Rochester, Minn., Coronary Artery Disease.
Nicholson J. Eastman, Baltimore, Complications of Pregnancy.
Sara M. Jordan, Boston, The Irritable Colon.
Charles A. Doan, Columbus, Ohio, Diagnosis and Treatment of Acute Leukemic States.
Alexander Brunschwig, New York, Carcinoma of the Cervix.

Dr. Hess will be the honored guest at the banquet Monday, 7 p. m., which will be preceded by a cocktail hour, 5:30-6:30 p. m. John C. Krantz Jr., Ph.D., professor of pharmacology, University of Maryland School of Medicine, Baltimore, will present "The Simplicity to Wonder."

University News.—The University of Tennessee College of Medicine, Memphis, recently announced the appointment of Dr. Walter Fleischmann of the Veterans Administration Hospital on Lamar Avenue as assistant professor in the division of pediatrics and of Dr. Michael L. Gompertz of the Veterans Administration Hospital (Kennedy) as instructor in the division of medicine.——Dr. Edward H. Storer, Seattle, has been appointed assistant professor of surgery and director of the Surgical Research Laboratories, succeeding Dr. James D. Hardy, who resigned to become chairman of the department of surgery at the University of Mississippi School of Medicine in Jackson. ——The following promotions are among those recently announced by the University of Tennessee College of Medicine: from associate professor to professor, Dr. James N. Etteldorf (pediatrics); from assistant professor to associate professor, Dr. James A. Taylor (psychiatry); from instructor to assistant professor, Dr. Arthur D. Weatherhead (psychiatry) and Dr. Arliss H. Tuttle (pediatrics); from assistant to instructor, Dr. Will R. Mitchum (medicine).——At the school of biological sciences Dr. Albert Hand and Dr. William S. Cheek, instructors in the division of pathology and microbiology, have been made assistant professors, and Hortense Louckes, Ph.D., instructor in the division of physiology, has also been advanced to assistant professor.——Dr. William H. Morse, formerly of Blytheville, Ark., who recently returned from six years' service in the Army, has joined the staff of University of Tennessee College of Medicine as a full-time instructor in the department of urology.——Emile Van Handel, Ph.D., of Rotherdam, Holland, has joined the staff as research associate in the division of physiology. He will continue his investigations on fat metabolism and the genesis of arteriosclerosis.

TEXAS

Examinations for Local Health Directors.—The Texas State Department of Health announces an examination for director, local health unit 1A (salary range: $9,720-$12,120; possibly higher in metropolitan health departments). Positions may be located anywhere in the state where a vacancy exists for a local health unit director. The minimum qualifications are (1) an M.D. degree and one year's internship in a recognized hospital; (2) an M.P.H. degree or certification by the American Board of Preventive Medicine; (3) two years of field experience after internship in general public health practice; (4) three years of additional experience in special training, teaching, or practice in preventive medicine and public health; and (5) licensure to practice medicine in Texas. Applicants must be citizens of the United States. All original appointments to permanent positions are made for a probationary period of six months. Examinations will be conducted continuously in Austin and in various centers over the state. Applications for this position may be sent, until further notice, to: Merit System Council, 814 Littlefield Bldg., Austin, or to Dr. Henry A. Holle, Commissioner of Health, Texas State Department of Health, 410 E. Fifth St., Austin.

WEST VIRGINIA

Symposium on Pneumoconiosis.—The second Symposium on Coal Workers Pneumoconiosis will be presented at Golden Clinic, Memorial General Hospital, Elkins, Oct. 4. Dr. Oscar A. Sander, associate professor of medicine, Marquette University School of Medicine, Milwaukee, will be general chairman. The guest speakers include Lawrence B. Berger, chief, health branch, Bureau of Mines, Pittsburgh; Dr. Edward A. Gaensler, visiting thoracic surgeon, Boston City Hospital; John C. Gilson, M.B., director, Pneumoconiosis Unit, England; Dr. Adolph G. Kammer, head, department of occupational health, graduate school of public health, University of Pittsburgh School of Medicine; Dr. Joseph E. Martin Jr., Elkins; Dr. Thomas Parran, dean, graduate school of public health, University of Pittsburgh School of Medicine; Dr. Frank Princi, Kettering Laboratory, University of Cincinnati College of Medicine; and Dr. David H. Waterman, Knoxville, Tenn. For hotel reservations and information write Dr. Joseph E. Martin Jr., Golden Clinic, Elkins (phone: Elkins 1220).

Chest Physicians Meet at White Sulphur Springs.—The annual meeting of the Potomac chapter of the American College of Chest Physicians will be held at the Greenbrier, White Sulphur Springs, Oct. 7. The following program will be presented at the morning session:

Morphological Changes in Tuberculosis, Milford L. Hobbs, Morgantown.
Pulmonary Manifestations of Systemic Disease, Harold S. Pettit, Charleston, S. C.
Mediastinal Tumors, Edgar W. Davis, Washington, D. C.

In the afternoon "Medical Aspects of Cardiac Valvulotomy" will be discussed by Dr. C. Edward Leach, Baltimore, and "Angiocardiography in the Diagnosis of Thoracic Disease" by Dr. Herbert E. Sloan, Ann Arbor, Mich. At the completion of the formal program in the afternoon, there will be a radiological conference, with Dr. Harold S. Pettit, Charleston, S. C., as moderator. Mr. Charles E. Hodges, Charleston, managing director of the Charleston Chamber of Commerce, guest speaker at the annual luncheon, will have as his subject "West Virginia, Your Host—What Do You Know About It?"

Rural Health Conference.—The eighth annual Rural Health Conference will be held at Jackson's Mill Oct. 6 under the sponsorship of the West Virginia State Medical Association and the auspices of its rural health committee (Dr. Charles E. Staats, Charleston, chairman), with the support and cooperation of the West Virginia Farm Bureau, the Farm Women's Council, the Agricultural Extension Division of West Virginia University, and the state department of health. Aubrey O. Gates, Little Rock, Ark., field director, A. M. A. Council on Rural Health, will serve at both the morning and the afternoon sessions as moderator for a panel composed of representatives of the West Virginia Farm Bureau, Farm Women's Council, Agricultural Extension Service, West Virginia State Medical Association, state department of health, West Virginia University Medical Center, 4-H clubs, Future Farmers of America, and Blue Cross-Blue Shield plans in the state. The topics to be considered include: mental health; public health protection; rural ambulance service; the new medical center at West Virginia University; farm safety; home safety; physician distribution in rural areas; foods and nutrition; need for dental health services; and the Blue Cross-Blue Shield program in West Virginia. The West Virginia State Medical Association will be host at a luncheon in the Mt. Vernon Dining Hall. Part of the proceedings will be televised and shown subsequently before interested groups in the state.

WISCONSIN

University News.—The regents of the University of Wisconsin Medical School, Madison, recently approved a $1,609,152 schedule of costs for an addition to Service Memorial Institutes, the medical building. The structure will be a six-story building, facing Linden Drive at Charter Street in the medical center of the Madison campus. Four floors and part of the basement will be devoted to the work of the anatomy department, now housed in Science Hall. A new student laboratory and the department of physiological chemistry will be located on the fifth floor.

Orthopedic Field Clinics.—The Bureau for Handicapped Children, state department of public instruction, announces the following schedule for orthopedic field clinics: Racine, Oct. 5-6; Eau Claire, Oct. 10-11; Sheboygan, Oct. 19-20; La Crosse, Oct. 25-28. The clinics are conducted for persons under 21 years of age who come within the state's definition of a crippled child. It is preferred that referral be made by the family physician, but when this is not feasible arrangements may be made by writing to the bureau. Inquiries should be addressed to the Bureau for Handicapped Children, 146 North, State Capitol, Madison 2.

HAWAII

Society News.—Michael Heidelberger, Ph.D., professor of immunochemistry, Columbia University College of Physicians and Surgeons, New York, recently addressed the Hawaii chapter of the Society of the Sigma Xi on "Antigens and Antibodies."——Dr. Robert S. Pollack of San Francisco spoke before the Honolulu County Medical Society on "Cancer of the Head and Neck."——Dr. Munawar Ali, president of the Pakistan Medical Association, accompanied by Mrs. Ali, stopped in Honolulu on their medical trip around the world.

Personal.—Dr. Richard K. C. Lee, Honolulu, president of the Territorial Board of Health, recently returned from a good will tour of Asia where, under the sponsorship of the International Education Exchange Program of the State Department, he lectured in Korea, Formosa, Hong Kong, Singapore, Malaya, and Indonesia.——The new commanding officer of the Tripler

Army Hospital, Honolulu, is Brig. Gen. John F. Bohlender, M. C., who came to Hawaii from Ft. Sam Houston, Texas. Dr. Bohlender served in Hawaii at the old Tripler Hospital between 1931 and 1934 and during World War II served in the South West Pacific.

GENERAL

Society News.—The interim meeting of the house of delegates of the **Association of American Physicians and Surgeons, Inc.**, at the LaSalle Hotel, Chicago, Oct. 7-8, will have as banquet speaker Friday at 7 p. m. Mr. William L. McGrath, Cincinnati, United States Employer Delegate to the International Labor Organization. All physicians who are eligible for membership in the American Medical Association and their wives are welcome at the banquet. Per plate charge is $6.

Awards in Tuberculosis.—At the annual meeting of the National Tuberculosis Association in Milwaukee, William H. Feldman, D.V.M., professor of pathology at the Mayo Foundation Graduate School of the University of Minnesota, Rochester, was awarded the Trudeau medal, given annually for meritorious contribution on the cause, prevention, or treatment of tuberculosis. The Will Ross medal, awarded annually for distinguished contribution to the tuberculosis control movement in a field other than the medical sciences, was bestowed on Frederick D. Hopkins, Ph.B., Glen Rock, N. J., retired NTA executive secretary.

Meeting of Obstetricians and Gynecologists.—The Central Association of Obstetricians and Gynecologists will hold its 23rd annual meeting at the Deshler-Hilton Hotel, Columbus, Ohio, Oct. 6-8, under the presidency of Dr. Frank L. McPhail, Great Falls, Mont. The guest speaker, Dr. Daniel G. Morton, Los Angeles, will discuss "The Making of the Obstetrician-Gynecologist" at the close of the Thursday morning session. The annual prize award paper, "The Cardiac Output During Labor" by Drs. Charles H. Hendricks and Edward J. Quilligan, Cleveland, will precede the presidential address at the close of the Friday morning session. In all, 18 presentations have been scheduled.

Annual Meeting of Medical Illustrators.—The Association of Medical Illustrators will hold its 10th annual convention at the Barbizon-Plaza Hotel, New York City, Oct. 1-5. A symposium on publication problems involving the doctor-author, illustrator, copy editor, engraver, and printer has been scheduled for Monday afternoon and "Discussion of the Professional Problems of the Medical Illustrator" for Tuesday afternoon. At 5 p. m. Monday there will be a cocktail reception and the formal opening of the exhibit at the Hotel Art Gallery, with welcome by the medical schools in the New York area. The annual banquet will be held at 7 p. m. Tuesday.

Meeting on Psychosomatic Medicine.—The Academy of Psychosomatic Medicine will hold its second annual meeting Oct. 6-8 at the Plaza Hotel in New York City. The subject of this year's scientific program is "The Psychosomatic Aspects of Drug Administration." There is no registration fee. Guests may attend the banquet. The speakers will include: Dr. Lester L. Coleman, New York (Wonder Drugs—A Psychosocial Phenomenon); Dr. Harry Kozol, Boston (Epilepsy: Modern Treatment with Drugs as a Keystone of Psychosomatic Method); Dr. George B. Koelle, Philadelphia (The Clinical Neuropharmacology of Mescaline and *d*-Lysergic Acid); Dr. Joseph E. F. Riseman, Boston (Experiences with Placebos in the Treatment of Angina Pectoris); Dr. Mark D. Altschule, Belmont, Mass. (Ideas About the Metabolism of Epinephrine); and Dr. M. Murray Peshkin, New York (Psychosomatic Aspects of Drugs in Allergy Practice).

Meeting of Medical Record Librarians.—The 27th annual conference of the American Association of Medical Record Librarians will meet at the LaSalle Hotel, Chicago, Oct. 3-7. Tuesday afternoon Dr. Jack Masur, assistant surgeon general, U. S. Public Health Service, Washington, D. C., will discuss "Growth and Development of a Profession," and Phillip E. Ryan, executive director, National Health Council, New York, will outline the program of that organization. Dr. Charles W. Mayo, Rochester, Minn., will speak at the banquet at 7 p. m. Dr. Albert H. Holland Jr., medical director, Food and Drug Administration, Washington, D. C., and George F. Archambault, chief of pharmacy branch, division of hospitals, Department of Health, Education and Welfare, Washington, D. C., will participate in a round-table panel Wednesday morning on the recording and reporting of drug reactions. Dr. Charles U. Letourneau, director of the program in hospital administration, Northwestern University Medical School, Chicago, will be a panel member for the true and false audience-participation program of human aspects of supervision on Wednesday. A tour of Chicago hospitals is scheduled for Friday morning.

Annual Conference on Rheumatic Diseases.—The third annual Midwest Conference on Rheumatic Diseases will be held at Henry Ford Hospital, Detroit, Oct. 5, under the sponsorship of the Michigan chapter, Arthritis and Rheumatism Foundation, and the Michigan Rheumatism Society and under the cosponsorship of the department of postgraduate medicine, University of Michigan Medical School, Ann Arbor; the Academy of General Practice; Michigan State Medical Society; Wayne University College of Medicine, Detroit; and the Wayne County Medical Society. The following program will be presented:

Diagnosis and Treatment of Rheumatic Fever, Currier McEwen, New York.
Gout, Charley J. Smyth, Denver.
X-Ray in the Diagnosis of Rheumatic Diseases, Paul C. Hodges, Chicago.
Osteoarthritis, Russell L. Cecil, New York.
Diagnosis of Rheumatoid Arthritis, Joseph L. Hollander, Philadelphia.
Treatment of Rheumatoid Arthritis, Joseph J. Bunim, Bethesda, Md.
Diagnosis and Treatment of Rheumatoid Spondylitis, Richard H. Freyberg, New York.
Back Pain, Carl E. Badgley, Ann Arbor, Mich.
Physical Medicine in Rheumatic Diseases, Edward W. Lowman, New York.
The Painful Shoulder, Otto Stein Brocker, New York.

Registration fee will be $5 except for interns, residents, and physicians in the service, who are not being charged a registration fee. Inquiries may be directed to the general chairman, Dr. John W. Sigler, Henry Ford Hospital, Detroit.

Annual Clinical Conference.—The 33rd annual fall clinical conference of the Kansas City Southwest Clinical Society will convene at the Municipal Auditorium, Kansas City, Mo., Oct. 3-6. Dr. Elmer Hess, Erie, Pa., President, American Medical Association, will deliver an address on Monday entitled "Can the General Practitioner Be a Urologist?" The Edward Holman Skinner Memorial Lecture, "Considerations Concerning the Roentgen Diagnosis of Carcinoma of the Lung," will be presented Saturday by Dr. Eugene P. Pendergrass, Philadelphia. Other guest speakers and their first presentations will include:

Oscar T. Clagett, Rochester, Minn., Esophageal-Hiatus Hernia.
A. Carlton Ernstene, Cleveland, Newer Therapeutic Tools in Cardiovascular Disease.
Frederick W. Fitz, Chicago, The Doctor and His Heart.
John H. Gilmore, Chicago, Roentgenographic Survey of the Abdomen.
James H. Growdon, Little Rock, Ark., Surgery in the Diabetic Patient.
Edwin F. Hirsch, Chicago, Variations of the Blood Lipids in Health and Disease.
William S. Middleton, Washington, D. C., Zoonoses.
Rudolf J. Noer, Louisville, Ky., Changing Concepts in Treatment of Intestinal Obstruction.
Edward H. Rynearson, Rochester, Minn., Varieties of Diabetes.
Theodore E. Sanders, St. Louis, Management of Acute Eye Emergency.
Harris B. Shumacker Jr., Indianapolis, Management of Acute Pancreatitis and Recurrent Pancreatitis.
Newton D. Smith, Fort Worth, Texas, Relationship of Anorectal Disease to General Medicine.
J. Robert Willson, Philadelphia, Practical Aids in Gynecologic Diagnosis.
Stewart Wolf, Oklahoma City, Gastrointestinal Tract of the Aged.

A clinicopathological conference and a conference on the management of diabetes have been scheduled, as have the following panels: Nonmalignant Lung Diseases; Postcholecystectomy Syndrome; Bleeding Gastrointestinal Lesions; Urinary Tract Infections; and Hormones and Newer Drugs—Their Use and Abuse. Operative clinics, clinical demonstrations, and a series on "How You Do It" will be presented on color television Sunday, Monday, and Tuesday.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories and possessions in the weeks ended as indicated:

CANADA

Meeting on Fertility.—*The second annual meeting of the Canadian Society for the Study of Fertility will convene at the Royal York Hotel, Toronto, Oct. 6-8. The sessions will open at 9 a. m. Thursday, followed by a panel discussion on the general practitioner's role in diagnosis and treatment of infertility. At 11 a. m. "Experience with Uterotubal Insufflation by a New Kymographic Insufflation with* Co_2 *Derived from an Effervescent Tablet; Demonstration of Apparatus and Graphs" will be outlined by Dr. Isidor C. Rubin, New York. A film, "The Physiology of Reproduction," and a film on ovulation in the rat (by permission of Dr. Richard J. Blandau, Seattle) will precede discussion at 3:15 p. m. of "Treatment of Female Sterility with X-Ray to the Ovaries and Pituitary with Special Reference to Congenital Abnormalities of the Offspring" by Dr. Ira I. Kaplan, New York. The Thursday session will end with "The Occurrence of Pregnancy with Very Low Sperm Counts" by Dr. Moses M. Braunstein, Montreal. Dr. John O. Haman, San Francisco, former* president, American Society for the Study of Sterility, will be chairman for the Friday morning program, including: "Impact of the Emotions on a Patient with Infertility" by Dr. A. Herbert Marbach, Philadelphia; "Effects of Psychic Stimuli on Uterine Contraction Patterns and Their Relationship to Fertility" by Dr. William M. Bickers, Richmond, Va.; and "Surgical Aspects of Male Sterility" by Donald Young, F. R. C. S. (E), Liverpool, England, for which the discussant will be Dr. Fred A. Simmons, Boston. The following program will be presented Friday afternoon:

Physiology of Endometrium in Relation to Conception, Edward C. Hughes, Syracuse, N. Y. (discussant, Clyde Randall, Buffalo)

Polycystic Diseases of the Ovaries, George A. Simpson, F.R.C.S. (C), Montreal.

Fertility Resulting from Pelvic Pyrexia Induced by Bipolar Intravaginal Diathermy, Abner I. Weisman, New York.

Saturday will be devoted to clinical demonstrations at Toronto hospitals. The convention fee of $10 includes registration and banquet charges. For information, write Dr. Earl R. Plunkett, Secretary-Treasurer, 469 Waterloo St., London, Ontario, Canada.

FOREIGN

Postgraduate Lectures in Madrid.—The Hospital Provincial de Madrid, Spain, announces the eighth course of medicosurgical postgraduate lectures, to be delivered Nov. 2-30 in the Hospital Provincial de Madrid, the Policlinica de Aparato Digestivo of the Faculty of Medicine of Madrid, and the Clinica de la Concepcion of Madrid. The topics are: "Darkness and Horizons of Digestive Pathology," "Functional and Organic Changes of the Biliary Tract," "Granulomatous Enteritis," and "Differential Diagnosis of True and False Acute Abdomen." There will also be a seminar, practical demonstrations on roentgen and endoscopic techniques and on clinical laboratory analysis, and a course on anesthesia and techniques in surgery of the digestive tract. Dr. Richard B. Cattell of the Lahey Clinic, Boston, will serve on the faculty. Applications for registration should be made to the Secretaria particular del Dr. C. Gonzalez-Bueno, calle de Villanueva, 12, Madrid, Spain, before Oct. 15.

CORRECTIONS

Residency Training in Psychiatry.—In the Internship and Residency Number of The Journal, Sept. 24, 1955, page 334, the following data should have been indicated for the residency training program in psychiatry: Veterans Administration Hospital, North Little Rock, Ark.: first year residencies offered, 4; total residencies offered, 12; length of approved program (years), 3.

Parts of Medical Center Completed.—In the news item in The Journal, Aug. 13, 1955, page 1375, entitled "Parts of Medical Center Completed," the statement was made that the Loyola University Stritch School of Medicine and College of Dentistry building was at present under construction. Dr. John F. Sheehan, dean of the school of medicine, writes to point out that as yet there is no construction under way and that present plans call for the erection of the new Stritch School of Medicine building in the northwest part of Chicago on a tract of land recently annexed from Skokie. The dental school, Dr. Sheehan states, will remain in its present location.

EXAMINATIONS AND LICENSURE

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: *Oral.* New York City, Oct. 23-27. *Written.* Various locations in United States and Canada, July 20, 1956. Final date for filing application is Jan. 20. Sec., Dr. Curtiss B. Hickcox, 80 Seymour St., Hartford 15.

American Board of Dermatology and Syphilology: *Oral.* Washington, D. C., Oct. 14-16. Final date for filing application was March 15. Sec., Dr. B. M. Kesten, One Haven Ave., New York 32, N. Y.

American board of Internal Medicine: *Oral.* Chicago, Nov. 30-Dec. 1. *Subspecialties. Cardiovascular Disease.* Chicago, Nov. 30. The closing date for acceptance of application for gastroenterology was Feb. 1, and for cardiovascular disease the closing date was June 1. Exec. Sec., Dr. William A. Werrell, 1 West Main St., Madison 3, Wis.

American Board of Neurological Surgery: *Oral.* New Haven, November. Oral examinations given in Spring and Fall. Final date for filing application for the Spring examination is October 1; for the Fall examination April 1. Sec., Dr. Leonard T. Furlow, Washington University School of Medicine, St. Louis 10.

American Board of Obstetrics and Gynecology: *Written Examination and submission of Case Reports. Part I.* Various locations in United States and Canada, and military centers outside of the Continental United States, Feb. 3, 1956. Final date for filing application is Oct. 1. *Oral and Pathological Examinations. Part II.* Chicago, May 11-20, 1956. Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6.

American Board of Ophthalmology: *Practical Examination.* Chicago, Oct. 3-7. Written. January 24-26, 1956. *Practical Examination.* San Francisco, June 18-21, St. Louis, Oct. 20-25. Applications for 1957 written examination must be filed before July 1, 1956. Sec., Dr. Merrill J. King, Box 236, Cape Cottage Branch, Portland 9, Maine.

American Board of Orthopaedic Surgery: *Oral.* Jan. 26-27. Final date for filing application was Aug. 15. *Part I. Oral and written.* Various centers, April 1956. Final date for filing application is Nov. 30. Sec., Dr. Harold A. Sofield, 116 South Michigan Ave., Chicago 3.

American Board of Otolaryngology: *Oral.* Chicago, Oct. 3-7. Final date for filing application is April. Sec., Dr. Dean M Lierle, University Hospitals, Iowa City.

American Board of Pathology: *Written and Practical.* Chicago, Oct. 6-8. Sec., Dr. William B. Wartman, 303 E. Chicago Ave., Chicago.

American Board of Pediatrics: *Oral.* Chicago, Oct. 7-9; and Washington, D. C., Dec. 2-4. Admin. Sec., Mrs. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Physical Medicine and Rehabilitation. *Parts I and II.* Chicago, June 16-17. Sec., Dr. Earl C. Elkins, 200 First St., S. W., Rochester, Minn.

American Board of Preventive Medicine: *Certification in Public Health.* Kansas City, Mo., Nov. 10-12. Sec.-Treas., Dr. Ernest L. Stebbins, 615 N. Wolfe St., Baltimore 5.

American Board of Psychiatry and Neurology: San Francisco, Oct. 17-18; New York City, December, Philadelphia, April 16-18, 1956. Sec., Dr. David A. Boyd, 102-110 Second Ave. S.W., Rochester, Minn.

American Board of Radiology: Chicago, Dec. 4. Final date for filing applications for the fall examination was July 1. Candidates who will complete their training by Dec. 31 will be eligible to appear for this examination. Sec., Dr. B. R. Kirklin, Kahler Hotel Bldg., Rochester, Minn.

American Board of Surgery: *Part I.* Centers throughout the United States, in Europe and in the Far East, Oct. 26 and March 28. Closing date for the October examination was July 1 and for the March examination is December 1. *Part II.* Chicago, Oct. 27-28; New York City, Nov. 14-15; St. Louis, Dec. 12-13; New Orleans, Jan. 16-17; Los Angeles, Feb. 13-14; San Francisco, Feb. 16-17; Durham, Mar. 12-13; Boston, May 14-15 and Philadelphia, June 4-5. Sec., Dr. John B. Flick, 255 S. Fifteenth St., Philadelphia 2.

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1955 Clinical Meeting, Boston, Nov. 29-Dec. 2.

1956 Annual Meeting, Chicago, June 11-15.

1956 Clinical Meeting, Seattle, Nov. 27-30.

1957 Annual Meeting, New York, June 3-7.

National Conference on Physicians and Schools, Moraine-on-the-Lake Hotel, Highland Park, Ill., Oct. 12-14. Dr. W. W. Bauer, 535 N. Dearborn St., Chicago, Director.

Academy of Psychosomatic Medicine, Hotel Plaza, New York, Oct. 6-8. Dr. Ethan Allan Brown, 75 Bay State Road, Boston 15, Secretary.

American Academy for Cerebral Palsy, Claridge Hotel, Memphis, Tenn., Oct. 10-12. Dr. Robert A. Knight, 869 Madison Ave., Memphis 3, Tenn., Secretary.

American Academy of Neurological Surgery, The Homestead, Hot Springs, Va., Oct. 27-29. Dr. Eben Alexander Jr., Bowman Gray School of Medicine, Winston-Salem, N. C., Secretary.

American Academy of Ophthalmology and Otolaryngology, Palmer House, Chicago, Oct. 9-14. Dr. W. L. Benedict, 100 First Avenue Bldg., Rochester, Minn., Executive Secretary.

American Academy of Pediatrics, Palmer House, Chicago, Oct. 3-6. Dr. E. H. Christopherson, 610 Church St., Evanston, Ill., Executive Secretary.

American Association of Blood Banks, Palmer House, Chicago, Nov. 19-21. Miss Marjorie Saunders, 3707 Gaston Ave., Dallas 10, Texas, Secretary.

American Association of Medical Clinics, Curtis Hotel, Minneapolis, Nov. 4-6. Dr. Edwin P. Jordan, Box 58, Charlottesville, Va., Executive Director.

American Association of Medical Record Librarians, LaSalle Hotel, Chicago, Oct. 3-7. Miss Doris Gleason, 510 N. Dearborn St., Chicago 10, Executive Director.

American Association for the Surgery of Trauma, Drake Hotel, Chicago, Oct. 27-29. Dr. James K. Stack, 700 N. Michigan Blvd., Chicago 11, Secretary.

American Clinical and Climatological Association, The Homestead, Hot Springs, Va., Oct. 31-Nov. 2. Dr. M. N. Fulton, 124 Waterman St., Providence 6, R. I., Secretary.

American College of Anesthesiologists, Hotel Statler, Boston, Nov. 4-5. Mr. John H. Hunt, 188 West Randolph St., Chicago 1, Executive Secretary.

American College of Cardiology Interim Meeting, Hotel Claridge, Memphis, Tenn., Nov. 10-12. Dr. Philip Reichert, Empire State Bldg., New York 1, Secretary.

American College of Gastroenterology, Hotel Shoreland, Chicago, Oct. 24-26. Dr. Joseph Shaiken, 33 West 60th St., New York 23, Secretary.

American College of Surgeons, Conrad-Hilton Hotel, Chicago, Oct. 31-Nov. 4. Dr. Michael L. Mason, 40 East Erie St., Chicago 11, Secretary.

American Dental Association, San Francisco, Oct. 17-20. Dr. Harold Hillenbrand, 222 East Superior St., Chicago 11, General Secretary.

American Heart Association, Yung Hotel, New Orleans, Oct. 22-26. Mr. Irving Hexter, 44 East 23d St., New York 10, Secretary.

American Medical Women's Association, Board Meeting, Netherlands-Plaza Hotel, Cincinnati, Nov. 11-13. Miss Lillian T. Majally, 1790 Broadway, New York 19, Executive Secretary.

American Public Health Association, Muehlebach Hotel and Municipal Auditorium, Kansas City, Mo., Nov. 14-18. Dr. Reginald M. Atwater, 1790 Broadway, New York 19, Executive Secretary.

American School Health Association, Hotel President, Kansas City, Mo., Nov. 14-18. Dr. A. O. DeWeese, 515 East Main St., Kent, Ohio, Secretary.

American Society of Anesthesiologists, Hotel Statler, Boston, Oct. 29-Nov. 3. Dr. J. Earl Remlinger Jr., Room 1101, 188 W. Randolph St., Chicago 1, Secretary.

American Society of Clinical Pathologists, Drake Hotel, Chicago, Oct. 10-15. Dr. Clyde G. Culbertson, 1040-1232 West Michigan St., Indianapolis, Secretary.

American Society for the Study of Arteriosclerosis, Hotel Sheraton, Chicago, Nov. 6-7. Dr. O. J. Pollak, P.O. Box 228, Dover, Del., Secretary.

American Society of Tropical Medicine and Hygiene, Somerset Hotel, Boston, Nov. 2-5. Dr. John E. Larsh Jr., Dept. of Parasitology, School of Public Health, Chapel Hill, N. C., Secretary.

Association of American Medical Colleges, New Ocean House, Swampscott, Mass., Oct. 24-26. Dr. Dean F. Smiley, 185 N. Wabash Ave., Chicago 1, Secretary.

Association of American Physicians and Surgeons, Chicago, Oct. 7-8. Mr. Harry E. Northam, 185 N. Wabash Ave., Chicago 1, Executive Secretary.

Association of Life Insurance Medical Directors of America, Hotel Statler, New York, Oct. 19-21. Dr. Henry B. Kirkland, P. O. Box 594, Newark, N. J., Secretary.

Association of Medical Illustrators, Hotel Barbizon Plaza, New York, Oct. 1-3. Miss Rose M. Reynolds, Univ. of Nebraska College of Medicine, Omaha 5, Neb., Corresponding Secretary.

Association of Military Surgeons of the U. S., Hotel Statler, Washington, D. C., Nov. 7-9. Colonel Robert E. Bitner, 1726 I St. N.W., Washington 6, D. C., Secretary.

Association of State and Territorial Health Officers, Hotel Washington, Washington, D. C., Nov. 6-12. Dr. Franklin D. Yoder, State Board of Health, Cheyenne, Wyo., Secretary.

Central Association of Obstetricians and Gynecologists, Deshler-Hilton Hotel, Columbus, Ohio, Oct. 5-8. Dr. Edwin J. DeCosta, Suite 602, 116 S. Michigan Ave., Chicago 3, Secretary.

Central Neuropsychiatric Association, The Broadmoor, Colorado Springs, Colo., Oct. 20-22. Dr. Hamilton Ford, 112 North Boulevard, Galveston, Tex., Secretary.

Central Society for Clinical Research, Drake Hotel, Chicago, Nov. 4-5. Dr. Robert H. Ebert, 950 East 59th St., Chicago 37, Secretary.

College of American Pathologists, Drake Hotel, Chicago, Oct. 10-15. Dr. Arthur H. Dearing, 203 N. Wabash Ave., Chicago 1, Executive Secretary.

Congress of Neurological Surgeons, Hotel Statler, Los Angeles, Oct. 27-29. Dr. Philip D. Gordy, 1007 Delaware Ave., Wilmington, Del., Secretary.

Delaware, Medical Society of, Delaware Academy of Medicine, Wilmington, Oct. 17-18. Dr. Norman L. Cannon, 621 Delaware Ave., Wilmington, Secretary.

District of Columbia, Medical Society of the, Hotel Statler, Washington, D. C., Oct. 10-12. Mr. Theodore Wiprud, 1718 M St., N.W., Washington 6, D. C., Executive Director.

Gerontological Society, Sheraton-Belvedere Hotel, Baltimore, Oct. 27-29. Dr. Nathan W. Shock, Baltimore City Hospitals, Baltimore 24, Secretary.

Gulf Coast Clinical Society, Pensacola, Fla., Oct. 27-28. Dr. Barkley Beidleman, 1750 N. Palafox St., Pensacola, Fla., Secretary.

Indiana State Medical Association, French Lick Springs Hotel, French Lick, Oct. 16-19. Mr. James A. Waggener, 23 East Ohio St., Indianapolis 4, Executive Secretary.

Inter-Society Cytology Council, Statler Hotel, Cleveland, Nov. 11-12. Dr. Paul F. Fletcher, 634 N. Grand Blvd., St. Louis 3, Secretary.

Interstate Post Graduate Medical Association of North America, Municipal Auditorium, Milwaukee, Nov. 14-17. Mr. Roy T. Ragatz, 207 Gay Bldg., Madison 3, Wis., Executive Director.

Kansas City Southwest Clinical Society, Municipal Auditorium, Kansas City, Mo., Oct. 3-6. Dr. W. M. Kitchen, 306 E. Twelfth St., Kansas City 6e, Mo., Secretary.

Midwest Conference on Rheumatic Diseases, Henry Ford Hospital, Detroit, Oct. 5. Dr. J. J. Lightbody, 7338 Woodward Ave., Detroit 2, Medical Director.

Midwestern Section of American Federation for Clinical Research, Thorne Hall, Northwestern University, and Drake Hotel, Chicago, Nov. 3. Dr. Robert J Glaser, Barnes Hospital, St. Louis 10, Secretary.

Mississippi Valley Trudeau Society, Hotel Savery, Des Moines, Iowa, Oct. 14. Dr. Harold G. Curtis, Sunny Acres, Cuyahoga County Tuberculosis Hospital, Cleveland 22, Chairman, Program Committee.

National Association for Mental Health, Indianapolis, Nov. 4-6. Mr. Robert M. Heininger, 1790 Broadway, New York 19, Director.

Oklahoma City Clinical Society Conference, Oklahoma City, Oct. 24-27. Dr. Charles E. Leonard, 512 Medical Arts Bldg., Oklahoma City 2, Secretary.

Omaha Mid-West Clinical Society, Hotel Paxton, Omaha, Oct. 24-27. Mrs. Anne K. Ramsey, 1031 Medical Arts Bldg., Omaha 2, Executive Secretary.

Regional Meetings, American College of Physicians:

- Billings, Mont., Oct. 7-8. Dr. Harold W. Gregg, 103 North Wyoming St., Butte, Governor.
- Charleston, S. C., Oct. 7-8. Dr. Robert Wilson, 165 Rutledge Ave., Charleston, S. C., Governor.
- Buffalo, N. Y., Oct. 14. Dr. John H. Talbot, 100 High St., Buffalo 3, N. Y., Governor.
- Madison, Wis., Oct. 15. Dr. Frederick W. Madison, 425 East Wisconsin Ave., Milwaukee 2, Governor.
- Louisville, Ky., Nov. 5. Dr. Sam A. Overstreet, 332 West Broadway, Louisville, Ky., Governor.
- Newark, N. J., Nov. 9. Dr. Edward C. Klein Jr., 6 S. Kingsman Rd., South Orange, N. J., Governor.

Society of Clinical Surgery, Hotel Roosevelt, New Orleans, Nov. 11-12. Dr. Frank F. Allbritten Jr., University of Kansas Medical Center, Kansas City, Mo., Secretary.

Southern Medical Association, Shamrock Hotel, Houston, Texas, Nov. 14-17. Mr. V. .O. Foster, 1020 Empire Bldg., Birmingham 3, Ala., Secretary-Manager.

Southern Society of Cancer Cytology, Houston, Texas, Nov. 14-17. Dr. J. Ernest Ayre, 1155 N.W. 14th St., Miami, Fla., Secretary.

Southwestern Medical Association, Phoenix, Ariz., Nov. 16-18. Dr. Celso C. Stapp, 800 Montana St., El Paso, Texas, Secretary.

State Medical Journal Conference, Chicago, Nov. 7-8. Mr. Alfred J. Jackson, 535 N. Dearborn St., Chicago 10, Director.

Tennessee Valley Medical Assembly, Read House, Chattanooga, Tenn., Oct. 3-4. Dr. Harry E. Jones, 109 Medical Arts Bldg., Chattanooga 2, Tenn., Secretary.

The Constantinian Society, Sheraton-Park Hotel, Washington, D. C., Oct. 26-29. Dr. C. F. Shook, P. O. Box 1035-36, Toledo 1, Ohio, Secretary.

Virginia, Medical Society of, Hotel Jefferson, Richmond, Oct. 16-19. Mr. Robert I. Howard, 105 West Franklin St., Richmond, Executive Secretary.

Western Orthopedic Association, The Reef, Honolulu, Hawaii, Nov. 7-10. Dr. Ivar J. Larsen, 1133 Punchbowl, Honolulu 13, Hawaii, Secretary.

Western Society of Electro-Encephalography, Westward Ho Hotel, Phoenix, Ariz., Nov. 10-12. Dr. Sylvester N. Berens, 902 Boren Ave., Seattle, Secretary.

FOREIGN AND INTERNATIONAL

Canadian Society for the Study of Fertility, Royal York Hotel, Toronto, Ont., Canada, Oct. 6-8. Dr. Earl R. Plunkett, 469 Waterloo St., London, Ont., Canada, Secretary.

Conference of International Union for Health Education of the Public, Rome, Italy, Apr. 27-May 5, 1956. Mr. Lucien Viborel, 92 rue St. Denis, Paris 1er, France, Secretary-General.

Congress of International Association of Limnology, Helsinki, Finland, July 26-Aug. 7, 1956. For information address: Dr. H. Luther, Snellmansgatan 16 C 36, Helsinki, Finland.

Congress of International Association of Logopedics and Phoniatrics, Barcelona, Spain, Sept. 3-7, 1956. Dr. J. Perello, Provenza 319, Barcelona 9, Spain, Secretary-General.

Congress of International Society of Hematology, Hotel Statler, Boston, Mass., U.S.A., Sept. 3-8, 1956. Dr. W. C. Moloney, 39 Bay State Road, Boston, Mass., U.S.A., Secretary.

Congress of International Society for Research on Anesthesia, Miami Beach, Fla., U.S.A., Mar. 12-15, 1956. For information write: Dr. R. J. Whitacre, 13951 Terrace Road, Cleveland 12, Ohio, U. S. A.

Congress of Latin Society of Ophthalmology, Madrid, Spain, April 24-28, 1956. For information address: Dr. Costi, Montalban 3, Madrid, Spain.

European Congress of Allergology, Florence, Italy, May 1956. Prof. Umberto Serafini, Largo della Gancia 5, Rome, Italy, Secretary-General.

European Symposium on Vitamin B_{12}, Hamburg, Germany, May 1956. For information write: Doz. Dr. H. Bauer, Nervenklinik. Hamburg-Eppendorf, Germany.

International Academy of Legal and Social Medicine, Plenary Conference, Genoa, Italy, Oct. 13-17. Prof. Domenico Macaggi, Institut de Medicine legale, Universite de Genes, Genes, Italy, President.

International Academy of Pathology, Cincinnati, Ohio, U. S. A., April 24-25, 1956. Dr. F. K. Mostofi, Armed Forces Institute of Pathology, Washington 25, D. C., U. S. A., Secretary.

International Colloquium on Chlorpromazine and Neuroleptic Agents in Psycotherapy, Ste Anne Clinic of Mental Diseases, Paris, France, Oct. 20-22. Prof. Jean Delay, College of Medicine of Paris, 1, rue Cabanio, Paris 14e, France, Chairman.

International Congress of Allergology, Rio de Janeiro, Brazil, S. A., Nov. 6-13. Dr. Bernard N. Halpern, 197 boulevard St. Germain, Paris 7^{e}, France, Secretary General.

International Congress of Anthropological and Ethnological Sciences, Philadelphia, Pa., U. S. A., Sept. 2-9, 1956. Dr. William N. Fenton, National Research Council, Division of Anthropology and Psychology, 2101 Constitution Avenue, Washington 25, D. C., U. S. A., Secretary-General.

International Congress on Diseases of the Chest, Cologne, Germany, Aug. 19-23, 1956. Mr. Murray Kornfeld, 112 East Chestnut St., Chicago 11, Illinois, U. S. A., Executive Director.

International Congress for the History of Science, Florence and Milan, Italy, Sept. 3-10, 1956. Dr. M. L. Bonelli, Instituto di Ottica, Arcetri, Florence, Italy, Secretary-General.

International Congress of Hydatid Disease, Athens, Greece, Sept. 14-18, 1956. Prof. B. Kourias, Croix-Rouge Hellenique, 1 rue Mackenzie King, Athens, Greece, Secretary-General.

International Congress of Internal Medicine, Madrid, Spain, Sept. 19-23, 1956. Dr. J. C. De Oya and Dr. J. Gimena, Hostaleza No. 90, Madrid, Spain, Secretaries.

International Congress of International College of Surgeons, Palmer House, Chicago, Illinois, U. S. A., Sept. 9-13, 1956. Dr. Max Thorek, 1516 Lake Shore Drive, Chicago, Illinois, U. S. A., Secretary-General.

International Congress of International Society of Bronchoesophagology, Buenos Aires, Argentina, S. A., Oct. 28-29. Dr. Juan Carlos Arauz, Cangallo 4015, Buenos Aires, Argentina, S. A., Secretary General.

International Congress of Neo-Hippocratic Medicine, Montecatini, Terme, Italy, May 20-22, 1956. Prof. P. Delore, 13 rue Jarente, Lyon, France, Secretary-General.

International Congress of Paediatrics, Copenhagen, Denmark, July 22-27, 1956. Professor P. Plum, Rigshospitalet, Copenhagen, Denmark, President.

International Congress of Physical Medicine, Copenhagen, Denmark, August 20-24, 1956. Dr. B. Strandberg, Kobenhavns amts sygehus i Gentofte, Dept. of Rheumatology and Physical Medicine, Hellerup, Denmark, Honorable Secretary.

International Congress of Radiology, Mexico, D. F., Mexico, July 22-28, 1956. Dr. Jose Noriega, Tepic 126 (2e piso), Mexico, D. F. 7, Mexico, Secretary General.

International Congress of World Confederation for Physical Therapy, New York, New York, U. S. A., June 17-23, 1956. For information address: Miss Mildred Elson, American Physical Therapy Association, 1790 Broadway, New York 19, New York, U. S. A.

International General Medical Congress, University of Rosario Medical College, Rosario, Argentina, S. A., Nov. 7-12. Dean Jose Imhoff, Santa Fé 3100, Rosario, Argentina, S. A., Chairman.

International Physiological Congress, Brussels, Belgium, July 29-Aug. 5, 1956. For information address: Prof. J. Reuse, Faculte de Medicine et de Pharmacie, 115 Boulevard de Waterloo, Brussels, Belgium.

International Professional Union of Gynecologists and Obstetricians, Madrid, Spain, Sept. 28-29, 1956. Dr. Jacques Courtois, 1 rue Racine, St-Germain-en-Laye (S and O), France, Permanent International Secretary-General.

North Queensland Medical Conference, Cairns, North Queensland, Australia, June 25-30, 1956. Dr. W. R. Horsfall, P. O Box 672, Cairns, N.Q., Australia, Secretary.

Pan American Congress of International College of Surgeons, Mendoza City, Argentina, S. A., Oct. 22-26. For information address: Secretary, Caseros Av. 2154, Buenos Aires, Argentina, S. A.

Pan American Congress of Ophthalmology, Santiago, Chile, S. A., Jan. 9-14, 1956. Dr. Rene Contardo, Huerfanos 930, Of. 74, Santiago, Chile, Secretary General.

Pan American Medical Social Convention, Bogota, Colombia, S. A., Oct. 15-22. Dr. Leopoldo E. Araujo, Avenida de los Presidentes Num. 506, Apartado 2589, La Habana, Cuba, Secretary.

Pan American Medical Women's Alliance, Santiago, Chile, March 6-13, 1956. For information address: Dr. Eva Cutright, 458 Beall Ave., Wooster, Ohio, U. S. A.

Venezuelan Congress of Medical Sciences, Caracas, Venezuela, S. A , Nov. 18-26. Dr. A. L. Briceno Rossi, Apartado 4412, Ofic. del Este, Caracas, Venezuela, S. A., Secretary General.

World Congress on Fertility and Sterility, Naples, Italy, May 18-26, 1956. For information address: Prof. G. Tesauro, S. Andrea della Dame, 19, Naples, Italy.

MAGAZINE–TELEVISION REPORT

The following list of current medical articles in mass-circulation magazines and forthcoming network television programs on medical subjects is published each week only for the information of readers of THE JOURNAL. *Unless specifically stated, the American Medical Association neither approves nor disapproves of the articles and programs reported.*

TELEVISION

Monday, Oct. 3

ABC-TV, 8 p. m. EDT. "TV Reader's Digest" drama is titled "Six Hours of Surgery" and tells of the "intense personal problems of five persons involved in a delicate heart operation on a 16-year-old boy."

NBC-TV, 9 p. m. EDT. "Medic" presents "And There Was Light," second of a two-part episode on postpartum psychosis. In this show, a young mother who sought psychiatric treatment after the birth of a baby conquers her illness and returns to her family.

ABC-TV, 9:30 p. m. EDT. "Medical Horizons" televises the activities of a physiological emergency team at the Sloan-Kettering Institute, Memorial Center for Cancer and Allied Diseases, New York. Presented in cooperation with the American Medical Association.

Wednesday, Oct. 5

NBC-TV, 11:30 a. m. EDT. "Home" presents "Medical and Health News with Howard Whitman."

Sunday, Oct. 9

NBC-TV, 3 p. m. EDT. "Dr. Spock"—Inaugural telecast of a new half-hour show on child care and development, featuring Dr. Benjamin Spock.

MAGAZINES

Collier's, Sept. 30, 1955

"The Doctor with 2,300 Patients a Day," by Robert Bendiner

Dr. Henry M. Friedman, public health inspector at the Port of New York, "has protected these shores from the kind of contagion that for centuries has traveled by ship." He has given swift physical examinations to thousands a day for so long that he often can make a diagnosis at a glance.

Look, Oct. 4, 1955

"VIP—The World's 100 Most Important People," by Donald Robinson

The author selects 8 men in the health field in his listing of the 100 most important people: Dr. Jonas Salk, Selman A. Waksman, John Enders, Dr. Hans A. Krebs, Dr. Bernard N. Halpern, Dr. Hans Selye, Tadeus Reichstein, and Bernardo A. Houssay.

Parade, Oct. 2, 1955

"The Doctors Who Try Our Patience," by Hannah Smith

In answer to a recent *Parade* article entitled "The Patients Who Drive Us Crazy," the author writes of such doctors as "Dr. Joyboy, the optimist" (who can't believe there is anything seriously wrong); "the triple tester" (who won't make a simple diagnosis without a battery of tests); "the jargon juggler" (who likes to keep things mysterious); "the man with the saw" (who performs unnecessary surgery); and others.

Redbook, October, 1955

"The Doctors Who Fell in Love," by Bob Willoughby and Wallace Croatman

A picture story showing the devotion—to their patients and to each other—of Dr. Will Kamprath and his wife, Dr. Coll Kamprath, who practice in the small town of Utica, Neb.

"How Safe Are School Lunches?" by Alice Lake

"Recent reports of disease outbreaks indicate that too often school lunches are making children sick." The author points out the hazards of mass food preparation and recommends that parents make sure that conditions are sanitary in their schools.

"Check List for Your Child's Health," by Alton L. Blakeslee

"Now—before the cold weather starts—is a good time to have your child examined by a pediatrician or your family physician." The author presents a list "designed to give you an advance idea of what points your doctor will cover in his examination, and also what he is likely to ask you about your child's health history."

Woman's Home Companion, October, 1955

"Abortion in America Today," by Morton Sontheimer

A discussion of legal and medical problems involved in both criminal abortions and legal abortions. "In America today decisions on legal abortions vary from doctor to doctor, from hospital to hospital. Doctors didn't create this fluctuating situation and they don't like it. It has been deposited in their laps by public indifference and vast national ignorance of our present abortion problem. . . . And linked to the legal or therapeutic abortion is the larger problem of criminal abortion. Most of these illegal operations are also performed by doctors, according to informed opinion."

Household, October, 1955

"When Should You Change Your Doctor?" by Lawrence Galton

The purpose of this article is "to emphasize the importance of understanding what good medical treatment is—whether the doctor is an outright bungler or a highly recommended physician who is capable, but who isn't helping as much as you might reasonably expect, with whom you don't get along well, or from whom you come away feeling frustrated."

Reader's Digest, October, 1955

"What the Doctor Sees in You," by J. D. Ratcliff

"Of all the diagnostic aids that scientific medicine depends upon today, the X-ray is one of the most vital." Mr. Ratcliff explains the various uses of this aid and cites examples of the progress radiology has made in recent years.

"Memphis Declares War on a Woman-Killer," by Lois Mattox Miller

The story of what the author calls "the boldest health crusade in history." National, state, and local groups promoted the mass examination of women in Memphis and Shelby County, Tenn., to find unsuspected cases of cancer of the cervix. Nearly 90,000 women responded, and of that number 1,800 were called back for further examination.

Family Circle, October, 1955

"Rheumatic Fever Can Be Curbed," by Ruth and Edward Brecher

"By means of wholehearted cooperation among teachers, parents, nurses, doctors, and heart associations . . . countless children are being protected from rheumatic fever—a disease that every year kills or disables more American children than polio." The article tells readers that "if your child has a sore throat, phone your doctor right away" and lists questions that such parents should be prepared to answer.

"Eat Your Way to Good Health," by Lawrence Galton

A report on how "nutritional therapy" is helping to fight various disease conditions. The article quotes the *Journal of Postgraduate Medicine* as saying: "Among some groups of patients it is likely that more than 50% could be helped by proper dietary advice. The public badly needs guidance from trained physicians in how to obtain better health through better nutrition."

GOVERNMENT SERVICES

ARMY

Physician Needed at Ordnance Depot in Alabama.—The position of civilian medical officer at the ordnance depot near Anniston, Ala., will become vacant Oct. 1 and applications for a successor are now being received. The successful applicant will be on a civil service status and receive a gross annual salary of $10,065 with paid vacations from 13 to 26 working days a year and 8 federal holidays. The regular tour of duty is eight hours a day, five days a week. The major duties of this position are the examination of employees and applicants, the first-aid treatment of injured employees, and the sanitary inspection of facilities. A staff of nurses and modern medical facilities are available.

This Army ordnance depot has a civilian strength of about 4,350 with 16 military officers and their families and no enlisted personnel. It receives, stores, and maintains automotive equipment and supplies and ammunition. It is located about 60 miles from Birmingham and 110 miles from Atlanta and covers an area of 16,000 acres. Adjacent to the depot are housing facilities for about 400 families at reasonable rental. The medical officer is encouraged to live in one of these residences, where he may supplement his salary by being available to the residents after duty hours. Applicants should address their letters to the Civilian Personnel Officer, Anniston Ordnance Depot, Anniston, Ala., on receipt of which arrangements will be made for interviews.

Color Television System for Army Medical Center.—The nation's first installation of compatible color television for hospital use will be made by the Radio Corporation of America to serve three government medical activities located at the Walter Reed Army Medical Center, Washington, D. C. The installation will provide three complete color television systems for use by the Armed Forces Institute of Pathology, the Walter Reed Army Hospital, and the Army Medical Service Graduate School. Contract for the color television system was awarded on the basis of a low bid of $425,800. Installation, now underway, is scheduled for completion early next year. The system will be operated by the Army Signal Corps. It will be available to other Defense Department agencies in the event of national emergencies. Ultimately, the system will be expanded to connect other governmental hospitals and military medical installations into a medical network for exchange of information and services. The independent but interconnected installation provides the government services with maximum flexibility and utilization of the color TV system. For example, it will be possible for a pathologist at the AFIP to view an operation at the Walter Reed Hospital two blocks away. If the removed tissue requires laboratory pathological investigation, it can be sent by pneumatic tube direct from the Walter Reed Hospital surgery to the AFIP. Then, while the surgeon who removed the tissue watches on his TV monitor, the pathologist can prepare the specimen for slide projection and hold a two-way picture and voice consultation with the surgeon. This initial application of compatible color television, operating over distances measured in city blocks . . . promises an eventual national medical TV network that will enable doctors, surgeons, and research scientists anywhere in the country to obtain directly the consultation services of specialists, demonstrations of latest advances in surgical and medical procedure, and advanced medical teaching.

ATOMIC ENERGY COMMISSION

New Director of Division of Biology and Medicine.—The U. S. Atomic Energy Commission announces the appointment of Dr. Charles L. Dunham as director of the commission's division of biology and medicine, effective Oct. 1. Dr. Dunham will succeed Dr. John C. Bugher, who will return to the Rockefeller Foundation, which recently announced his appointment as director of medical education and public health. Dr. Dunham has been deputy director of the division since July, 1954. Appointment of Dr. Charles W. Schilling as deputy director of the division succeeding Dr. Dunham also was announced. Dr. Shilling joined the commission in July, 1955, on his retirement as captain, Medical Corps, U. S. Navy. Dr. Shilling had served in the Navy for 28 years and was widely known for his role as senior medical officer in the rescue of personnel from the stricken submarine Squalus in 1939.

NAVY

Course for Reserve Officers.—A course in Medical Aspects of Special Weapons and Radioactive Isotopes for active and inactive regular and reserve medical department officers will convene at the Naval Medical School, Bethesda, Md., on Monday, Oct. 3, 1955, and continue to Saturday, Oct. 15. The first week of instruction will be on Medical Aspects of Special Weapons and Radioactive Isotopes with particular reference to personnel casualties from atomic explosions. During the second week professional and administrative topics will be presented including a symposium on reserve medical programs.

Inactive reserve medical department officers desiring to attend should submit their request for 14 days' training duty to their commandant's office at the earliest practicable date. Messing facilities are available. BOQ facilities are limited and will be available on a first-come, first-served basis only. The commandants of the first, third, fourth, fifth, sixth, eighth, and ninth naval districts and Potomac River naval command have each been assigned a quota for this course. Officers of the medical department on active duty may be given "authorization orders" (at no expense to the government). Orders should direct reporting to the commanding officer, U. S. Naval Medical School, NNMC, Bethesda, Md., prior to 4 p. m., Sunday, Oct. 2, 1955; officers will be detached on Saturday morning, Oct. 15, 1955. Officers availing themselves of this training are requested to assure that an advance copy of orders issued be forwarded to the reporting activity as early as possible.

VETERANS ADMINISTRATION

Rehabilitation of Aged Veterans.—Veterans Administration launched a program on Sept. 8 of planned living to rehabilitate aged veterans in its domiciliary "homes." The new program is designed to rehabilitate as many domiciliary members as possible to enable them to become productive citizens again in their home communities. For those not susceptible to this type of rehabilitation, the program is designed to enable them to enjoy their remaining years more fully with security and dignity, VA said. This program will be applicable to the 17,000 members presently receiving sheltered care in the 17 VA domiciliaries. Domiciliary members are disabled veterans who are so incapacitated that they are unable to earn a living but do not require full-time nursing or hospital care. Most domiciliary members are in the older age brackets.

The new program has three objectives: (1) to provide a place where eligible disabled veterans can live under conditions that will promote health and contentment, (2) to furnish authorized articles and services that they are unable to provide for themselves, including necessary medical care and hospitalization, and (3) to institute rehabilitation measures so as to enable each disabled veteran to return to his community or, where this is not possible, to function at maximum capacity in domiciliary status. The program will have an activity planning board that will draft an individual plan for each member. This daily plan of living will be based on a full medical evaluation and will be supplementary to prescribed medical care by contributing to medical and social rehabilitation objectives. VA said members will be encouraged to apply for jobs in which they have had previous experience or for which they may become qualified through training. These jobs may be in the domiciliaries themselves, or in VA hospitals or centers. When they are sufficiently rehabilitated to leave the domiciliaries as members, they may be employed by VA as regular civil service employees if they qualify or they may seek employment elsewhere with the assistance of the U. S. and state employment services.

DEATHS

Albus, William Reuben ⊕ Chicago; born in Catawissa, Pa., Dec. 5, 1893; Rush Medical College, Chicago, 1933; interned at the Presbyterian Hospital; surveyor for the joint commission on accreditation of hospitals attached to the American Hospital Association; formerly a member of the professional field staff of the Council on Medical Education and Hospitals of the American Medical Association; served in the medical reserve corps of the U. S. Army from 1934 to 1947, retiring with the rank of colonel; was a bacteriologist interested in the Lactobacillus acidophilus action in milk, for which he was elected a member of the Cosmos Club; died Sept. 10, aged 61, of cerebral vascular accident.

Auld, Frank Parkinson, Shelbyville, Ill.; Barnes Medical College, St. Louis, 1903; at one time district health superintendent of the state department of health; died July 16, aged 79.

Berner, Frank ⊕ New York City; Universität Basel Medizinische Fakultät, Switzerland, 1924; also a graduate in pharmacy; member of the American Psychoanalytic Association, American Psychosomatic Society, American Psychiatric Association, and the American Orthopsychiatric Association; for many years on the faculty of Columbia University College of Physicians and Surgeons; associated with the Neurological Institute; died in the Lenox Hill Hospital Aug. 4, aged 60, of multiple myeloma.

Bopp, Henry William ⊕ Terre Haute, Ind.; Indiana Medical College, School of Medicine of Purdue University, Indianapolis, 1906; member of the American Society of Plastic and Reconstructive Surgery; past-president of the Vigo County Medical Society; for six years deputy coroner; chairman emeritus of the executive committee of the Union Hospital; died July 27, aged 74, of cerebral vascular accident, bronchiectasis, and chronic pulmonary fibrosis.

Butt, Miriam M. ⊕ Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1894; an associate member of the American Medical Association; fellow of the American Academy of Ophthalmology and Otolaryngology; on the staff of the Woman's Hospital; died May 19, aged 82, of cerebral thrombosis and arteriosclerosis.

Clark, John Hubert, Knoxville, Tenn.; Meharry Medical College, Nashville, 1940; interned at the George W. Hubbard Hospital of Meharry Medical College, Nashville, where he served a residency; member of the city planning commission; on the staff of the Knoxville General Hospital; died July 27, aged 40, of acute myocardial infarction.

Coffee, Henry Daniel ⊕ Columbia, S. C.; Atlanta School of Medicine, Ga., 1909; served during World War I; for many years associated with the Veterans Administration; died in the Veterans Administration Hospital July 18, aged 68, of ruptured aortic aneurysm.

David, James Carleton ⊕ San Jose, Calif.; Northwestern University Medical School, Chicago, 1950; interned at the Highland-Alameda County Hospital in Oakland, where he served a residency; died May 21, aged 44.

Evans, Morris, San Francisco; Cooper Medical College, San Francisco, 1903; died in Millbrae, Calif., Aug. 14, aged 81.

Garnier, Anna M., New York City; Woman's Medical College of the New York Infirmary for Women and Children, New York City, 1893; for many years physician and surgeon for the American Manufacturing Company at its Greenpoint plant in Brooklyn; died Aug. 9, aged 85.

Goodloe, Aareiel Ellis, Chattanooga, Tenn.; University of the South Medical Department, Sewanee, 1909; served during World War I; died Aug. 2, aged 69.

Havel, Harold William, Ingleside, Neb.; Creighton University School of Medicine, Omaha, 1933; died July 17, aged 45.

Isaacs, George W., Faucett, Mo.; St. Louis College of Physicians and Surgeons, 1893; died in the Missouri Methodist Hospital, St. Joseph, June 11, aged 84, of arteriosclerosis.

Johnson, Frank Bruce ⊕ Lincoln, Neb.; Keokuk (Iowa) Medical College, 1894; died in Kearney July 23, aged 90.

Johnson, Hubert Hatch ⊕ Royal Oak, Mich.; Detroit College of Medicine, 1905; also a graduate in pharmacy; at one time health officer of Ypsilanti, Mich.; served on the staff of the Highland Park (Mich.) General Hospital; died in Wy-Curt Hospital Aug. 3, aged 83, of acute pyelonephritis.

Kacso, Ladislaus ⊕ Westlake, Ohio; Magyar Királyi Pázmány Petrus Tudomanyegyetem Orvosi Fakultasa, Budapest, Hungary, 1920; died June 7, aged 63.

Ladas, Harilaos Elia ⊕ Mobile, Ala.; National University of Athens School of Medicine, Greece, 1915; on the attending staff, Mobile Infirmary and Providence Hospital; died July 3, aged 65, of chronic glomerulonephritis.

Leviton, Nathan David, Chicago; Northwestern University Medical School, Chicago, 1911; died Aug. 16, aged 70.

Lowry, Henry Lawrence ⊕ Tindall, Mo.; Barnes Medical College, St. Louis, 1904; died in Trenton May 5, aged 86, of arteriosclerosis.

Maercklein, Ivan Rudolph, Minot, N. D.; Milwaukee Medical College, 1903; died in the Veterans Administration Hospital in Long Beach, Calif., April 27, aged 74, of cancer.

Owsley, Robert Wright ⊕ San Marino, Calif.; Indiana University School of Medicine, Indianapolis, 1934; member of the American Academy of Ophthalmology and Otolaryngology; specialist certified by the American Board of Otolaryngology; served during World War II; past-president of the Arcadia Community Chest and Lions Club of Arcadia; on the staff of the St. Luke Hospital in Pasadena; died in Stanford-Lane Hospital, San Francisco, Aug. 15, aged 43, of coronary occlusion.

Place, Philip Wilfred, South Lincoln, Mass.; Tufts College Medical School, Boston, 1909; served in France during World War I; for many years physician with the Grenfell Mission in Labrador; died in the Emerson Hospital in Concord July 30, aged 72.

Reagan, Charles Harold, Grundy, Va.; Northwestern University Medical School, Chicago, 1930; died July 3, aged 55, of acute coronary occlusion.

Reedy, Walter Marion, Dunmore, Pa.; Jefferson Medical College of Philadelphia, 1892; served on the staffs of the State and Mercy hospitals in Scranton; died June 8, aged 85, of carcinoma of the prostate.

Sanders, Samuel Robert ⊕ Moulton, Ala.; Birmingham Medical College, 1908; died June 17, aged 83, of cerebral hemorrhage.

Tate, Wendell Maurice ⊕ Peabody, Kan.; University of Kansas School of Medicine, Kansas City, 1933; member of the American Academy of General Practice; interned at the Halstead (Kan.) Hospital; on the staff of the Axtell Christian Hospital in Newton, where he died July 12, aged 49, of coronary occlusion.

Trader, Charles Bell ⊕ Sedalia, Mo.; Kansas City (Mo.) Medical College, 1901; died in the Bothwell Hospital July 21, aged 85, of heart block and nephritis.

Vandeman, Adelbert N., Spring Valley, Ohio; Starling-Ohio Medical College, Columbus, 1909; served during World War I; member of the Ohio State Medical Association; died Aug. 5, aged 76, of complications due to burns.

Williams, Louis A., Denver; University of Colorado School of Medicine, Denver, 1912; died in St. Anthony's Hospital July 24, aged 66, of cerebral vascular accident.

Wynkoop, James Cartright ⊕ Washington, D. C.; University of Maryland School of Medicine, Baltimore, 1892; died Aug. 3, aged 87.

⊕ Indicates Member of the American Medical Association.

AUSTRIA

Colectomy for Constipation.—At the meeting of the Society of Physicians in Vienna on June 24, Dr. R. Oppolzer reported on a woman, aged 30, who underwent appendectomy in 1942. Eight years later she began to complain of retention of feces of 14 days' duration, skin rash, folliculitis, and headache. Despite the use of laxatives and enemas, her bowels moved only once every 8 to 10 days. In 1951 she went for 16 days without a bowel movement despite enemas and laxatives. In 1952 she was admitted to the polyclinic where a hemicolectomy on the left side, including the left flexure and an anastomosis between the transverse colon and the sigmoid, was performed. Clinical improvement was noted, but bowel movements occurred only every second or third day and after laxatives. The condition of the patient remained bearable for two years; then she had severe headache and constipation increased again. In 1954 she had a retention of feces for 18 days despite repeated enemas, administration of neostigmine, paravertebral block, administration of acetylcholine, carbachol (Doryl), and posterior pituitary injection. On x-ray examination, the barium's position in the transverse colon remained unchanged for several days, although the anastomosis was free and wide.

Cure of constipation resulted from total colectomy with anastomosis between the ileum and the pelvic rectum, which was performed in September, 1954. Following operation the patient had daily bowel movements, but her headache continued for about four weeks, although an objective cause for it could not be discovered. Only phenolization of the carotid arteries on both sides by injections of 5% isophenol solution caused the prompt disappearance of the headache. The patient had been completely free from complaints for nine months when last seen. The microscopic examination of the colon revealed proliferation of the myenteric plexus. No narrowed portions and no changes in the submucosal plexus were observed.

At the same meeting, H. Finsterer said surgical treatment is indicated to relieve constipation only after internal treatment has failed. The type of surgical treatment depends on the cause of the constipation. In patients with megacolon or spasm of the descending colon and sigmoid, left-sided hemicolectomy with side-to-end anastomosis between the mobilized descending colon and rectum may be sufficient. Total removal of the pelvic colon may be necessary to prevent recurrence of the constipation, which was cured permanently in one patient only after resection of the spastically contracted colon. Total colectomy is preferably performed in two stages (first a left hemicolectomy, and, if constipation continues, extirpation of the right colon with ileorectostomy). Of the patients operated on recently, one patient is completely free from complaints and has normal bowel movements, but another complains of diarrhea. Constipation may cause the same symptoms as a gastric ulcer, and the apparent gastric disturbance may disappear permanently only after colectomy.

A woman, aged 56, who had been suffering from constipation since her childhood and who recently complained of stomach pains was admitted for an operation on her stomach. The speaker recommended colectomy, but the patient asked for gastrectomy because her husband, who had had a gastrectomy for an ulcer, had made a complete recovery and no longer was constipated. In December, 1924, the patient had a gastrectomy (Billroth 1). The postoperative course was satisfactory at first but, because of shrinking of the anastomosis, stenotic vomiting occurred. A second operation was performed on April 27, 1925 (posterior gastroenterostomy and cholecystectomy). After this operation the patient no longer vomited but the pain persisted. She was then treated by internists for a peptic jejunal ulcer. This treatment was ineffective, and she requested another operation on the stomach and threatened to commit suicide. She was operated on for the third time on Oct. 26, 1925. No ulcer was found in the stomach, but duplication of the colon on the splenic flexure and spasm of the descending colon and of the sigmoid were observed. Consequently, hemicolectomy was performed on the left side and the stomach was not disturbed. The patient made a complete recovery. She was seen in January, 1939, at which time she had no complaints, had normal bowel movements daily, and had gained 55 lb. (24.9 kg.). This patient could have been spared the operation on the stomach if she had submitted at once to the colectomy.

Wolff-Parkinson-White Syndrome.—At the same meeting, Dr. H. Dittrich reported on a man, aged 52 years, who was admitted to the medical department of the Hanusch Hospital for homologous serum hepatitis. In the course of the routine examinations an electrocardiogram was taken that showed the pattern of the Wolff-Parkinson-White syndrome. Repeated electrocardiograms made alternately with two different types of apparatus (one with direct recording and the other with photographic recording) showed that the altering of the electrocardiographic tracings could be reproduced only by the direct recorder. The cause of this surprising observation was that the patient had to walk to this apparatus, while the recordings with the other type of apparatus were made with the patient in bed.

DENMARK

Changes in the Causes of Death.—Frandsen and Hamtoft in *Ugeskrift for læger* for July 28, 1955, present tables that bring out some curious facts concerning the causes of death and disease from year to year. Between 1921 and 1954 deaths from suicide, cancer, heart disease, and vascular diseases of the central nervous system have grown enormously in number, while deaths from tuberculosis and other infectious diseases have become comparatively rare. Of every 100 deaths in 1954, 7 were violent, as compared with only 3 in 1921. Between these two years deaths from cancer have risen from 12 to 21 per 100; deaths from heart disease from 10 to 27; and deaths from vascular diseases of the central nervous system from 5 to 13. Only 1% of all the deaths in 1954 could be traced to tuberculosis, whereas 9% were due to this cause in 1921. Under the age of 25, from one-half to one-third of all the violent deaths in 1954 were due to traffic accidents, but, between the ages of 25 and 65, suicides among men constituted about half of all the violent deaths. For women of this age, the preponderance of suicide as a cause of violent death was even more marked. Between 1945 and 1953 there was a sharp rise in the number of patients treated in hospitals for digestive, circulatory, and gynecologic diseases. Diseases of the nervous system, tumors, and trauma also showed a marked rise. On the other hand, the number of patients with skin and infectious disease, including venereal disease, fell from 175 per 1,000 in 1945 to 70 per 1,000 in 1953. The average number of days spent in hospital by patients with medical ailments in 1953 was 22 days per patient, compared with only 15 for patients with surgical diseases. This average was 73 days for patients suffering from tuberculosis.

Acetazoleamide for Cardiac Edema.—Dr. Ib. Persson has treated 26 patients between the ages of 29 and 88 suffering from cardiac edema associated with arteriosclerosis. In addition to rest in bed, digitalis, and a salt-poor diet, they were given acetazoleamide and some mercurial diuretic alternately. Two tablets (each 250 mg.) of acetazoleamide were given three times a day, and in a few cases three such tablets were given three times a day over a short period. No serious ill-effects apart from slight lassitude in a few patients followed the administration of the new drug, but its action as a diuretic appeared to be somewhat weaker than that of a mercurial diuretic. Because mercurial diuretics may be poorly tolerated by some patients, acetazoleamide may prove a useful alternative. There are also some patients in whom a mercurial diuretic fails to eliminate the edema,

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

and in such patients alternate treatment with these two diuretics may be effective. Furthermore acetazoleamide may be given orally, hence the patient may take it at home (*Nordisk medicin* for May 12, 1955).

Poliomyelitis Vaccination.—Effective July 1, 1955, poliomyelitis vaccination was limited to children of school and preschool age. The vaccine is issued by the State Serum Institute in Copenhagen, and vaccination could be undertaken by any fully qualified physician. For this the physician is paid by the state four Danish crowns for each of the three injections given. There is no cost to the person vaccinated. The vaccinating physician is required to fill in a special form to serve as a certificate of vaccination, and, because the amount of vaccine available is limited, vaccinators are requested to send in their reports as promptly as possible. The vaccine is given intracutaneously. If the vaccine is given subcutaneously by mistake it will do no harm but is likely to do little good. The interval between the first and second injection is four weeks and between the second and third injection about 12 months. Each intracutaneous injection on the forearm should give rise to a well-defined, circular, anemic papule, with a diameter of 7 to 9 mm. In permitting any fully qualified physician to administer poliomyelitis vaccine, the Danish public health authorities have once again affirmed their policy of giving the general practitioner as much responsibility as possible with regard to public health measures.

Training of Specialists.—The Danish physician who wishes to qualify as a specialist attaches himself to certain hospitals of high standing and serves them for a prescribed period. He is not required to pass a formal examination. In 1920 only 15% of the medical profession in Denmark were recognized specialists, but by 1954 the percentage was 30. In recent years there has been a splitting up of the specialties for, while in 1930 there were only 15 different subjects in which a physician could specialize, this number had risen to 21 in 1954. Dr. Mogens Fog in *Ugeskrift for læger* discusses the pros and cons of the current system. He pays tribute to the high standards of his compatriots but warns against the loopholes for slipshod work by would-be specialists, some of whom suffer from a lack of systematic organization of their studies. At present the prospective specialist can master the technical side of his work without acquiring the perspective conferred by a scientific and biological approach. For want of such a background he may not be fully qualified to follow the evolution of his specialty. Without imposing formal examinations, as is the practice in the United States, the situation may be improved by providing lectures and organizing small study groups to review recent advances in the basic sciences.

Danish Cancer Register.—The *Danish Medical Bulletin* for July, 1955, has an account of the work of the Danish Cancer Register by its chief Johannes Clemmesen, who explains how closely his net is woven for catching every case of cancer. When the Register was opened in 1942, its principal tasks were defined as the provision of (1) reliable morbidity statistics with a view to the accurate estimate of therapeutic results, (2) an accurate estimate of differences in incidence of cancerous diseases at various times and in various areas, occupations, and other categories, and (3) statistics on individual patients for the use of physicians as well as for the study of multiple cancers and coincidence with other diseases. Cancer not being a reportable disease in Denmark, the aid of hospital services and individual physicians was sought to discover every case. The hospitals agreed to report patients with malignant disease to the Register at a token fee of 1 Danish crown for each case. In 1943 these reports cost about 9,000 of the total of 32,000 crowns spent by the Register in this year. In 1953 the cost of these reports had risen to 18,000 and the total cost to 95,000 crowns. The clerical staff originally numbered only two, but by January, 1955, it had expanded to one part-time and five full-time members. The filing card system in use during the early life of the Register has now been replaced by the full use of a mechanical tabulation system. Clemmesen insists that it would be fatal to consider cancer registers as merely institutes for the collection of statistical material. He believes that cancer registers will fail to fulfill their tasks if they are not put into a position to supplement the regional mapping out of cases of cancer by the collection of additional information related to particular problems. In recent years cancer registers have been developed in a number of countries following different systems, but the issue of success or failure may not in some cases lie entirely within themselves. In many cases their sponsors have sought their justification in the procurement of therapeutic statistics, hoping that endemiological studies could thrive alongside the former. It is, however, feared that therapeutic statistics with their careful studies of relatively small differences in percentage of cures may outgrow the germs of endemiological research and not least in places where the leadership is not in the hands of medical men familiar with the problems of malignant diseases.

Blood Transfusion Problems.—The donors of the blood bank of the Bispebjerg Hospital in Copenhagen are largely recruited from Copenhagen, and they consist chiefly of persons paying their debt of blood for relatives benefiting from blood transfusion in this hospital. Kryger and Schaebel in *Ugeskrift fo læger* for July 21, 1955, tabulate the 498 mishaps observed i the course of about 25,000 transfusions. Although none of th mishaps were fatal, several were alarming. Three cases of sever hemolytic reaction reflected mistakes in technique that migh have been avoided. A comparatively mild hemolytic reactio may be indicated by shivering and a rise of temperature. Thi may be the only clinical sign of such a reaction, but it shoul be taken as a warning of more trouble on the resumption o a transfusion. Among the 107 patients with an allergic reactio such as urticaria (96 cases) or asthma, 3 had severe shock tha might well have proved fatal had not epinephrine been give intravenously. A febrile reaction was recorded in 284 patient and diverse other reactions, such as pain in the loins, in 10 cases. Citrate reactions and speed reactions are not include in this study as the blood bank was not examined in respect t them. A comparison of the findings of this study with thos of earlier studies published abroad shows that the frequenc of hemolytic reactions is lower in Denmark than elsewher This difference may indicate that the population of Denma has received less artificial immunization than that of other cou tries. If so, there may in the near future be a rise in the fr quency of blood transfusion complications due to the increa in immunization of the population.

National Diabetes Association.—In a report for 1954, t National Diabetes Association referred to the opening of t Skaerven summer colony for diabetic children as the outstan ing event of 1954; 118 such children were given a three wee outing in 1954. The association also runs the only convalesce home for diabetics in Denmark, with 24 beds available the ye around. Another center in Copenhagen provides a home f diabetic children between the ages of 2 and 14 whose ow homes cannot give them the special care necessary for diabetic

International Congress of Surgery.—For the first time in i history, the International Congress of Surgery was held in Scandanavian country. More than 1,000 surgeons from 4 different countries, including Russia, met in Copenhagen i July. *Nordisk medicin* for July 21, 1955, celebrated the oc casion with a series of articles in English on surgery in Denmark Finland, Norway, and Sweden.

ENGLAND

Effects of Anesthesia on the Brain.—The brain is extremel vulnerable to short periods of vascular insufficiency or anoxia Dr. P. D. Bedford has investigated the mental condition of 25 persons over the age of 65 after operations performed unde general anesthesia (*Lancet* 2:259, 1955). In 120, or 48%, ther was some evidence of mental impairment, and 29 of these, o 12% of the total, were suffering from severe dementia that wa not present before and that would not normally have been associated with the operation. Eighteen of the patients showed extreme dementia. Typically, anesthesia comprised preoperative medication with 20 mg. of Pantopon, or 10 to 15 mg. of morphine, and 0.4 mg. of hyoscine, or 0.65 mg. of atropine, followed by induction with thiopental used intravenously, and continuation with nitrous oxide and oxygen, or ether and oxygen, or trichloroethylene and oxygen. For abdominal operations a muscle relaxant was often given. Histological examination of the brains of those who died was not very helpful, as it was difficult to distinguish the degenerative changes of old age from those of anoxia.

Dr. Bedford does not directly incriminate the anesthetic agents and drugs used as the cause of these catastrophes, because not all the older people were affected. There must be an individual susceptibility to one or more of the factors concerned in operation with the patient under general anesthesia that determines the occurrence of brain damage. This susceptibility is unpredictable and fortunately rare. Operations on older people should only be performed when absolutely necessary. Premedication and postoperative medication should not be given routinely. Narcotics and potent analgesics are known to affect the central nervous system and should be given only when indicated. Less potent drugs should be used whenever possible. Blood pressure, hemoglobin, and oxygenation should be kept at optimum levels in operations, and "hypotensive surgery" should be absolutely forbidden in the elderly. Dr. Bedford makes a plea for the careful anticipation, prevention, and treatment of the complications of operations performed with the patient under general anesthesia, such as dehydration, mineral depletion, vitamin deficiency, pneumonia, postoperative toxemia, and fever. When postoperative confusion occurs in older people, its cause and the reason for its precipitation should be sought.

Dr. Bourne of St. Thomas' Hospital has also pointed out that nitrous oxide anesthesia can cause grave effects in the young as well as the old (*Lancet* **2**:295, 1955). Between 4,000 and 5,000 dentists in the United Kingdom have known patients of all ages, including young children, to remain in coma after the administration of nitrous oxide. He has followed up 70 such patients, and 2 of these suffered cerebral damage after receiving nitrous oxide for dental extraction.

Health in the Services.—A report on the health of the Army (Report on the Health of the Army, W. O. Code No. 11055, 1954) indicates that medical discharges in the Army for psychiatric disorders were 4.1 men per 1,000 strength; in the women's services the figure was 15 per 1,000. Discharges for all other diseases were 9.1 men per 1,000, and in this group tuberculosis was highest with 1.2 per 1,000 followed by peptic ulcer with 1.1 per 1,000. Discharges of Army recruits during processing show a similar pattern. Total discharges were 8.75 per 1,000 intake, nearly one-half of which were for psychiatric disorders. There was a high incidence of appendicitis and peptic ulcer, both of which have been increasing. The incidence of appendicitis among women in the Army was three times as great as among men, although peptic ulcer was less common among the women. Sickness rate in the Army, as measured by admissions to hospital and other medical units, was 274 per 1,000 over a period of two years. The principal causes of admission were tonsillitis, pharyngitis, and skin conditions. The common cold was low on the list. In the British Army in Germany skin conditions were the commonest cause of admission. Venereal diseases accounted for 5.5. per 1,000 strength among the hospital admissions in the United Kingdom,15.3 in the British Army on the Rhine, and 13.4 in the Middle East. The highest incidence occurred in the Korean war zone.

The Air Force findings (Report on the Health of the Royal Air Force, By Command of the Air Council, A. P. 3319/51) were slightly different. Discharge for psychiatric reasons was highest, as in the Army, but was 21% of the total. Next came diseases of the ear and mastoid (21%) and then all forms of tuberculosis (11.6%). In the Women's Royal Air Force 43% of total disability discharges were for psychiatric reasons. The incidence of tuberculosis was similar to that for men (12%). Among the men 703 contracted scarlet fever and 839 streptococcic sore throat. Most of these were returned to duty. The incidence of poliomyelitis declined in the R. A. F. but not in the Army and that of chicken pox and measles went up. There was a striking increase in scarlet fever from 0.71 to 2.76 per 1,000 strength and in rubella from 1.91 to 3.70. The incidence of diphtheria was low everywhere, and that of typhoid was negligible except in the Middle East. Before the war the disability discharge rate was 5.6 per 1,000 in the Air Force, but then all personnel were volunteers. The National Service Act has changed the health and age pattern of the forces. The average number of days' sickness has improved compared with prewar records, and the death rate (2.2 per 1,000) is just over half what it was before the war.

Health Center for Old People.—Three years ago the public health department of Rutherglen, a suburb of Glasgow, started a welfare service for old people to maintain them in a sound state of physical, mental, and social well-being. To do this it was necessary to provide clinical facilities for assessment at the premises of the local authority, cooperate with the statutory and voluntary services for old people, extend the health visitor's work, and set up a chiropody service. The aim of the center was to promote health rather than cure disease, compile a register of old people, search for early cases of disease, integrate treatment with social environment, and conduct research into the aging process. A health officer sees new patients, interviews any old patient returning for guidance, and carries out general clinical and medicosocial assessments. He arranges for radiological examinations and discusses each patient's problems over a cup of tea. A consultant physician holds a weekly clinic, examines in detail the patients sent by the health officer, and arranges for the necessary diagnostic or laboratory tests. Close contact is maintained between the center and the patient's general practitioner. Visiting nurses attend the clinic to learn of the problems of old age, and voluntary workers teach the old people occupational therapy. Physiotherapists and a chiropodist employed by the local authority attend the clinic. When further investigation is thought necessary, the patient is admitted to a hospital, certain wards of which are devoted to the care and treatment of the old. In two years 500 ambulant old people attended the clinic; 352 of these suffered from some disability. Pain, weakness, dyspnea on exertion, and giddiness were common complaints and were experienced by 89% of the patients. The systolic pressure was over 170 mm. Hg in 313 patients, and in 85 the hypertension was asymptomatic. The hemoglobin level was 80% or more in 395 of the patients, and in only 9 was it less than 60%. Medical and surgical treatment was given where necessary. The mental health was also investigated. About 125 were unhappy, and attempts were made to improve their morale by various means. Physiotherapy and the occupational therapist contributed much to this improvement. Unhappiness was commonest in those who lived alone; indeed, many were virtually socially isolated. It is pointed out that if child welfare clinics are still necessary, then the need for health centers for old people is even more necessary, because their age group has been left behind in the general advance of the public health services.

Congress of Obstetrics and Gynecology.—At the 14th British Congress of Obstetrics and Gynecology, held at Oxford in July, Dr. A. Walker of London said that in Britain about 60% of confinements for childbirth were in hospitals and that 80% in and out of hospitals were managed by midwives. Less than 10% of general practitioners who practice obstetrics care for as many as 20 cases a year. Over half undertake antenatal care only and rarely see a baby born, and, of those on call for the delivery of a baby, only about 20% attend the confinement. Conditions are different in rural areas. A smaller body of physicians practicing obstetrics as specialists is needed, handling enough cases to retain their interest and skill. These specially trained physicians could hold permanent part-time hospital posts under the supervision of consultants. Dr. Walker considered that midwives should have status and responsibility—particularly as 80% of babies are delivered by midwives in Britain—and that they should be the ones to manage normal labor. He thought the present system in Britain was sound and that it would be a waste of medical manpower to replace the midwife. There are already too many practitioners competing for too little obstetric work.

Dr. G. F. Abercrombie of London, speaking as a family practitioner who had delivered 768 babies, favored hospital delivery for the primagravida because of the high rate of operative procedures needed in delivery. The general practitioner-obstetrician should be competent in external version, breech delivery, surgical induction of labor, manual rotation of the head, forceps extraction, manual removal of the placenta, and the repair of lacerations. Even so, some 5% of women in labor need attention that can only be given in a hospital, such as a cesarean section or blood transfusion. The physician should give the patient an understanding of the physiology of pregnancy and labor before the event. Most multigravidas can be delivered at home, but every primagravida undergoes what is in effect a trial labor. She should therefore be delivered in a hospital with all facilities provided, after which she could return home early so that the specialist-practitioner could care for her. The speaker deplored the fact that in London general practitioners did not have access to hospital obstetric units. Prof. A. M. Claye of Leeds said that domiciliary obstetrics should be a thing of the past. All patients should be hospitalized, as it is impossible to forecast a normal delivery.

Admission of Preschool Children to Hospitals.—A joint committee of the Institute of Child Health, the Society of Medical Officers of Health, and the Population Investigation Committee, has been investigating the admission of preschool children to hospitals. Their report states that the annual admission rate of children from one month up to 5 years of age is 53 per 1,000. Nearly half remained in the hospital for one week or less, and a third stayed longer than a fortnight. The main causes of admission in the first year of life were congenital malformations, digestive diseases, and respiratory infections. By the age of 2 years tonsillectomy accounted for a quarter of the admissions and bacterial infections for 10%. More boys than girls were admitted at all ages, mainly on account of congenital malformations, digestive diseases, circumcision, and accidents. Children from homes in the lower income group had a higher rate of admission for infections than did those from homes of the professional classes and white-collar workers. There were no marked social differences in other disorders, except for a small group of unskilled manual workers' children who had a high rate of admission for all causes, except tonsillectomy. The greater incidence of infections among manual workers' children was attributed to the prevalence of large families and overcrowding in such social groups and the consequent greater risk of infection. One third of all the children were admitted to wards or hospitals that allowed no visiting, not even by parents. This ruling is now relaxed in most, if not all, hospitals. In 1953 the Central Health Services Council advocated the daily visiting of children in hospitals by their parents, and the Ministry of Health sent out a directive urging this, provided there were adequate safeguards against the spread of infection. Apparently, Scottish hospitals have always been more lenient in allowing visitors to children's wards. Correspondence in the national press reveals that there is still much public uneasiness over the attitude of some hospitals that do not permit the frequent visiting of children by their parents. The Hospital for Sick Children, Great Ormond Street, one of the best known children's hospitals in the country, strongly favors the visiting of sick children by their mothers between 5 and 6 p. m., so that they can help the nursing staff at the children's bedtime.

Death of Lord Horder.—Lord Thomas Jeeves Horder, physician to five English monarchs, died on Aug. 13 of a heart attack. He was born in Shaftesbury in 1871. His scientific and medical education was received at the University of London and St. Bartholomew's (Bart's) Hospital. He supplemented his formal studies in biology by a correspondence course in which his papers were marked by H. G. Wells. After obtaining his M.D. degree he soon established himself on Harley Street and was appointed to the visiting staff of Bart's Hospital, where he became the senior consultant. Early in his career he was called in to attend King Edward VII, and this began his connection with the English royal family. The Duke of Windsor, when he was Edward VIII, made Lord Horder his physician, and he was the extra physician to King George V, George VI, and to the Queen. He was knighted in 1918, made a baronet in 1923, and raised to the peerage in 1933. He was made a Knight Commander of the Victorian Order and eventually a Grand Commander. He was one of the last of a generation of clinicians reared in the school of experience without laboratory or diagnostic aids. His reputation was based on his brilliance as a diagnostician and on his understanding of patients, who included politicians, prize fighters, and Barbara Hutton. He was chairman of the Cremation Society, Anti-Noise League, Empire Rheumatism Council, and British Empire Cancer Campaign. During World War II he was a consulting physician to the War Office, Ministry of Food, and Ministry of Pensions. Lord Horder was a determined opponent of the National Health Service, as originally outlined by Mr. Aneurin Bevan and the socialist government. Throughout the protracted negotiations between the Ministry of Health and the medical profession he succeeded in obtaining numerous concessions. As chairman of the Fellowship for Freedom in Medicine he carried on the battle against the politicians and spoke and wrote right up to the end against the National Health Service, which he maintained lowered the professional standards of medicine.

Health Services in Scotland.—The health services in Scotland and the care of the aged sick were debated in the House of Commons on July 19. Mr. Willis, a member for Edinburgh, said that of 5,000 old people examined, 40% were in need of care and attention. If this number represents a true cross section of the population, about 200,000 old persons are in need of nursing care, hospital treatment, therapy, or rehabilitation. Of the 990 in the survey living alone, 537 or 10% of the total are bedridden or unable to fend for themselves. Mr. Thomas Oswald, another Edinburgh member, said that 25% of the old people in this survey were in need of medical attention, and this need was not being met. A further 25% require home or domestic help, and 10% needed physiotherapy, which they are not receiving. About 12% need institutional care, and, for this, 152 are on waiting lists. In reply the Secretary of State for Scotland said that more beds were being set aside for the aged and that special units were being set up in Dundee and Glasgow. A special training school for nurses is to be opened in Glasgow. Visiting nurses, too, are being called on to give advice to the elderly sick, and practically all local authorities are providing a service of domestic helps. The hospital building program is being put into effect. It was noted that the death rate from tuberculosis had fallen from 23 per 100,000 in 1953 to 20 last year. Even so, over 7,000 cases were reported in 1954. The average stay in hospital has been reduced, largely due to the use of new chemotherapeutic drugs, and more patients are now cared for without entering the hospital. For the whole of Scotland there are still just under 500 patients with tuberculosis waiting for admission to a hospital. When compared with the figure of 9,000 admissions annually, this does not seem large.

Energy Requirements of Miners and Sedentary Workers.—A continuous record was made of the nature and duration of every activity, both at work and at home, of 19 miners and 10 clerks at Buckhaven, Scotland (Special Report Series, Medical Research Council, No. 289, London, Her Majesty's Stationery Office, 1955). This was done by noting their food intake and oxygen consumption, as measured by the Kofranyi-Michaelis respirometer, an instrument devised by workers at the Max Planck Institut fur Arbeitsphysiologie at Dortmund, Germany. The miners expended an average of 3,660 calories a day and the clerks 2,800. The difference was due to the energy expended at work (1,750 and 890 calories a day respectively). The two groups used the same number of calories on their spare-time activities. The proportions of calories derived from protein, fat, and carbohydrate were about the same in the two groups. The miners did not get their extra calories from carbohydrates alone. Contrary to what was expected, the miners spent 38% of their working time sitting about. The metabolic cost of the various mining activities was 7 calories per minute, but the mean rate of energy expenditure during the entire time spent on the underground shift was only 4.3 calories per minute. None of the miners had energetic recreations. Taking the week as a whole both at work and at home, the miners spent two-thirds of their total time and more than one-third of their total energy lying down or sitting up. A similar finding is reported for Army cadets by McCance and Widdowson of Cambridge. Alleged to be spending lives of tremendous activity, they spent nine and one-half hours a day sitting and eight and one-half hours in bed.

Wrong Hospital.—The *Lancet* of July 30 describes the case of a small boy who suffered an injury to his eye and was sent away from the eye hospital to which he was taken because it was an extraocular injury, from the accident hospital because there was no fracture, and from the infirmary because he was a child. He was then taken to the children's hospital, from which he was sent to the plastic surgery unit at the regional hospital. This extreme specialism of hospitals, whereby the patient in urgent need of attention is given the run-around, is deplored. The lay press has also reported many instances of the ill being sent from one hospital receiving room to another before being admitted. When such a patient dies soon after admission, even though this outcome is not connected with the transfer from one hospital to another, the two are often connected in the public mind. The *Lancet* contrasts the case of the boy with that of an elderly man far from home on a motor tour who was suddenly afflicted with acute urinary retention. Rather than be admitted to a strange hospital he traveled home in easy stages and stopped to obtain relief whenever he saw a hospital. He progressed from catheter to catheter until he reached his home town and the physician of his choice. During his journey he stopped at cottage hospitals, city infirmaries, a maternity hospital, and a mental hospital. At all, his distress was relieved. The *Lancet* comments that at all these hospitals the physicians, surgeons, general practitioners, obstetricians, and psychiatrists were all doctors first and specialists second and were not so highly specialized that they had forgotten how to pass a catheter.

Structure of Vitamin B_{12} Elucidated.—At the annual meeting of the Chemical Society at Exeter in July, Sir Alexander Todd of Cambridge University announced that the structure of vitamin B_{12} had been elucidated as a result of collaborative work with the Glaxo Laboratories at Greenford in Middlesex, Dr. D. M. Hodgkin of Oxford, and workers at the University of California. Further alkaline hydrolysis of cobalt-containing acid hydrolysis products by the Cambridge workers resulted in the isolation of a hexacarboxylic acid. Dr. Hodgkin described the results of x-ray crystallographic analysis of this at the third International Congress of Biochemistry at Brussels in August. Coupling this with the observation that acid hydrolysis of vitamin B_{12} yielded the phosphate of 5:6 dimethylbenziminazole ribofuranoside, Sir Alexander Todd considers that the vitamin is the nucleotide of a complex containing four pyrrole rings, the nitrogen atoms of which are coordinated with a cobalt atom. He acknowledges the parallel research going on in the Merck Laboratories in New Jersey. Their workers have isolated degradation products, which permitted the inclusion of several more atoms in the four pyrrole-ring structure. They have been submitted to x-ray crystallographic analysis by Dr. Hodgkin. Experiments on the synthesis of vitamin B_{21} have been started at Cambridge. A synthesis would be of academic interest only, as it could not compete with the present method of manufacture by which vitamin B_{12} is made as a by-product in the manufacture of streptomycin.

Separation of Children from Their Parents.—In recent years much interest has been focused on the connection between the separation of child and parents and the subsequent development of delinquency and emotional disturbances in the child. An investigation was carried out by Howells and Layng to test the validity of this association (*Lancet* 2:285, 1955). Two groups of children were examined—a random group of disturbed children who were attending a child psychiatric clinic, and a control group of mentally healthy school children. The parent was asked for details on each occasion that separation between child and parent had occurred before the child's fifth birthday. Sex distribution, average age, the pattern of separation experiences, and the low incidence of separation were about the same in the two groups. The observations did not bear out the generally accepted view that the early separation of child from its parents is responsible for later psychiatric disturbances. The findings supported the impression that mental ill health in children springs from processes arising from being with their parents rather than from being away from them. Children enduring adverse home environments may actually gain from separation from their parents. Although separation may cause suffering for the child, it does not, in most cases, lead to mental ill health. Some children enjoyed and benefited from separation. When separation from the mother is inevitable, emotional trauma can be reduced by using friends or relatives as mother substitutes.

Genetic Damage from Irradiation.—There is great alarm that nuclear explosions may produce undesirable genetic changes in man. The possible genetic dangers of the therapeutic and diagnostic use of roentgen rays have, however, been largely overlooked. For example, it has been stated that the irradiation of the ovaries for the treatment of amenorrhea may cause induced mutations affecting future generations. Stanford and Vance investigated the dose of roentgen rays received by the gonads from various diagnostic procedures (*Brit. J. Radiol.* 28:266, 1955). The dose varied from 0.026 milliroentgens for radiographic examination of the forearm to 800 milliroentgens for lateral radiography of the lumbosacral joint. In men, for similar procedures, the dose received by the testes varied from 0.13 to 1,100 milliroentgens per exposure. The average gonadal dose per exposure is of the order of 35 milliroentgens for men and 65 milliroentgens for women. An estimate of the possible genetic effects can be calculated from these figures. If it is assumed that the background radiation over a generation is about 3 r, then an average of one diagnostic roentgenogram per person per generation would increase the mutation rate due to radiation—and the tendency to genetically determined deaths from this in later generations—by about 0.01 in men and 0.02 in women. These calculations are based on the assumption that the field area is reduced to a minimum when taking roentgenograms.

Unusual Epidemic.—An unusual epidemic in Carlisle, Cumberland, is described by Dr. Wallis in *Lancet* (2:290, 1955). Sporadic cases were first noted early this year, and a few are still appearing. The main features are conjunctivitis, which may be unilateral, fever up to 104 F, malaise, sore throat, dry cough, and enlarged cervical lymph glands. The acute phase lasts for a week to 10 days, and convalescence is marked by severe listlessness that persists for several weeks. Investigations were carried out on 60 patients. No abnormal total or differential leukocyte counts were obtained, nor were any abnormal cells discovered. The heterophil antibody test was consistently negative, as were routine complement-fixation tests against influenza viruses A and B, Q fever, psittacocis, venereal lymphogranuloma, and mumps V and S antigens. Some serums were tested and found negative for Toxoplasma infection. Bacteriological examination of throat and feces, when warranted by physical signs, revealed no abnormality. Throat washings, conjunctival swabs, and specimens of feces investigated at the Virus Reference Laboratories, Colindale, London, have been negative for antibodies against the "adenoidal-pharyngeal-conjunctival" or "acute respiratory disease" group of viruses. All ages and both sexes were affected. The incubation period was between five and 10 days. Laboratory investigations are still being carried out on new cases.

Amputation Due to Gas Gangrene.—Damages of $5,600 were awarded on July 29 to a woman, aged 39, whose arm had to be amputated after a fall following which gas gangrene developed. In addition, her husband was awarded $5,600 for the loss of her services owing to her disabilities. Both the patient and her husband sued the South-West Metropolitan Regional Hospital Board, the West Dorset Group Hospital Management Committee, and the physician concerned for negligence in treatment, which was denied by all parties. An unpadded plaster was applied to the arm, the radius and ulna of which were fractured; the broken fragments had caused a small puncture wound. Good practice demanded that a compound fracture, such as this was, should not be enclosed at once in an unpadded cast. Penicillin or some other antibiotic should also have been administered. Severe interference with the circulation of the blood resulted from the plaster being too tight. The arm began to swell, and it was claimed that the plaster should have been split, although this was not done. The arm finally had to be amputated. The judge did not blame the physician for not suspecting or diagnosing gas gangrene, but he said that the fitting of a close and unpadded plaster immediately after the reduction of the fracture interfered with circulation, creating a condition favoring infection.

Rockefeller Grants.—Grants from the Rockefeller Foundation for the second quarter of the year exceeded $5,600,000. In Britain and the Commonwealth the two major benefactions to medicine were a five year grant of $314,000 for the medical faculty of the University College of the West Indies, Jamaica, to help expand the research and teaching program based on the study of local diseases and health problems and $156,000 for laboratory facilities at Oxford for the new Regius Professor of

Medicine, Prof. G. W. Pickering. The costs of a sabbatical year at Oxford for an American professor of physiology were also paid, as were two grants to two British universities, one to support Prof. L. S. Penrose's research on human genetics and another to Queen's University, Belfast, to help Prof. G. W. A. Dick's investigations on viruses. The foundation has also announced a five year grant for the establishment of a nurse teaching unit at Edinburgh University, which would be the first of its kind to be formed within a British university. The court of Edinburgh University graciously accepted the gift, and a committee has been appointed to establish the unit, which would prepare teachers and administrators in the nursing profession, with the object of providing a regular supply of well-trained nurses.

Breast Feeding.—Hytten and Thomson (*Brit. M. J.* 2:232, 1955) examine the incidence and duration of breast feeding in the Aberdeen area. In all parts of Great Britain the official policy is to promote breast feeding whenever possible, yet its success varies from one area to another. The incidence of successful breast feeding was defined as the proportion of babies wholly fed on the breast during the first three months of life. After three months mothers commonly introduce supplementary feedings, and it is difficult to know what contribution breast milk is making to the child's total food intake. The present study was based on records of 2,404 babies born in maternity hospitals, nursing homes, and private homes. At the age of three months 35.6% of the infants were wholly breast fed, and after six months 24.5% were still feeding from the breast, although most were receiving supplementary food at this time. After discharge from hospital the older mothers nursed their babies longer than did the younger ones. At three months only 25% of mothers aged 20 or less were still breast feeding, compared with 39% of women over 30. The incidence of breast feeding was higher after the second than after the first pregnancy and then declined with increasing parity. After breast feeding had been established its maintenance was largely determined by good maternal health and favorable social circumstances. There was a comparatively high incidence (45%) at three months in women whose babies were delivered at private nursing homes. Physical condition and living conditions were also factors. Of women graded as having good physique and health, 40% breast fed their babies for three months, compared with 31% of those graded fair and 23% of those graded poor. Where the housing conditions were such that there was one person per room, the incidence of breast feeding at three months was 42%. This fell to 28% when there were more than two persons per room. At four months the growing infant may require sufficient milk daily to supply 1,100 calories. This means that a moderately active mother who is lactating needs over 3,000 calories daily. Relatively few women have the appetite for this. It is also cheaper, as many poorer mothers have found, to feed the baby directly with dried cow's milk because the latter obtained through the National Health Service costs about one-tenth of that supplied through breast feeding. Thus breast feeding, once established, is most likely to be successfully maintained by healthy women who take and have the appetite for a sufficient diet, who can take the care of a baby in their stride, and who do not suffer from intercurrent morbidity. These circumstances are more common in the well-developed and educated women in the upper social groups.

Medical Liaison with Uganda.—A liaison between the pediatric services of Uganda and those of the Hospital for Sick Children, Great Ormond Street, London, has recently been inaugurated. A senior resident from the Hospital for Sick Children has been sent to Uganda for a two year period, to be followed in turn by further residents. In addition two nurses from the hospital volunteered to go out and take charge of the children's wards for a similar period. Each year one of the hospital specialists will pay a month's visit to Uganda. The purpose of the visit is to study the problems of tropical pediatrics, since many postgraduate students from tropical countries attend special courses at the Hospital for Sick Children, where their special problems are not always understood. It is also hoped that the visits will improve the care of the sick African child by introducing up-to-date methods. The scheme has been promoted with the financial assistance of the Colonial Office and the cooperation of Makerere College at Kampala. The experience obtained by the visiting physicians and nurses will widen their horizon and increase their responsibility. Disease in the tropics is often encountered in the raw and florid state not seen in British hospital practice.

Suicides.—In his report of 1954, Dr. D. H. Geffen, health officer for Hampstead, examines the causes of the high suicide rate in this suburb of London. In 1950 Hampstead had the highest suicide rate in the country—28.7 per 100,000 population. In the following years the rate fell, but it is still high. Dr. Geffen attributes this to the relatively high proportion of the population in the upper social groups and upper income levels. He also remarks that a high proportion of the population of Hampstead, as in other areas with a high suicide rate, live in lodgings, boarding houses, or rooms. Some of these people may be those who leave their own home towns and come to London in search of employment. Dr. Geffen says that, although it is popularly supposed that a person who threatens to commit suicide seldom does so, all such threats should be taken seriously, and the public should have less easy access to dangerous medicines in lethal quantities. Referring to fashions in methods of suicide, which he refers to as a mentally infectious disease, Dr. Geffen deplores the publicity given to such methods in the popular press.

Prefrontal Leukotomy and Legal Responsibility.—One of the risks of prefrontal leukotomy is that the patient's sense of responsibility and his social values may be reduced. This was in evidence during the trial of a man charged with stealing cigarettes at Bristol. The accused admitted stealing the cigarettes from his employers. The trial, however, was postponed pending a medical report, when it was learned that the man had become irresponsible after a prefrontal leukotomy four years previously. Before this he had been a good worker, with employment for 28 years in one position, but three months after he had left hospital he was discharged as unsatisfactory. He had since been divorced and had been frequently seen wandering about with no fixed address. In spite of the medical evidence, the man was fined $11.20 by the magistrates for stealing.

Illegal Accouchement.—According to Section 9 of the Midwives Act, 1951, it is an offense punishable by a fine of up to $28 for any person, male or female, to attend a woman in labor, unless this is done under the direction and personal supervision of a qualified medical practitioner. This does not apply to medical students or midwives, nor to cases where attention is given in emergency because of unavailability of a physician. This section of the Midwives Act was invoked in a case before the courts. A man claiming that he was a "natural healer" and a diet reformer was prosecuted on July 28 for attending his wife in childbirth and for delivering the baby himself. The man stated that it was the second child he had delivered. A fine of $8.40 was imposed.

ITALY

Morbidity in a Sanatorium.—According to Teriggia and Baroni in *Notiziario Sanitario* (18:2 [March 2] 1955), 39 cases of tuberculosis occurred among the personnel of the Sondalo Village Sanatorium over a seven year period and among an average of 1,250 persons in charge of the patients. The highest rate of tuberculous morbidity was observed in 1952 with 11.4 cases per thousand. During the first two years (1947 and 1948) no cases had been observed. The highest rate of morbidity (6.1 to 6.6 per 1,000) occurred in persons in their second to fourth year of seniority in the sanatorium. Most cases occurred in persons in the 24 to 30 year age group. The disease occurred in one physician and 10 nurses, with a rate of 6.2 per thousand, and in the male employees, with a rate of 5.5 per thousand. The above rates of morbidity are lower than those reported in similar sanatoriums in Italy and other countries.

PERU

Nutritional Guide for Mothers.—The enormous incidence of malnutrition among infants, especially of the poorer classes, constitutes one of the most pressing problems facing the Ministry of Public Health and Social Welfare. Although an energetic campaign to improve the situation has been carried on by the Central Organization of Social Assistance, a voluntary agency founded by Mrs. María Delgado de Odría, wife of the President of Peru, the results to date have been disappointing. The lack of education of most of the mothers has prevented their effective cooperation. For this reason, the nutrition department of the Ministry of Health has prepared a nutritional guide especially for mothers of the lower classes. In this project Dr. Martha Trulson of Harvard University has acted as a technical adviser. The peculiar feeding habits and the foods commonly used in each rural area have been considered, so that the mother, wherever she is, can feed her child in the best way possible according not only to her social and economic conditions but to the ecologic conditions of the place where she lives.

Society of Public Welfare.—At the meeting of the Society of Public Welfare of Lima in July, Dr. Oswaldo Hercelles reported that the budget of the institution for 1955 was about $3,295,522. In Peru most social welfare functions, including hospitalization of medically indigent, are still in the hands of voluntary welfare organizations, whose main support comes from lotteries and rentals. Although the total budget for 1955 is $195,125 higher than for 1954, the deficit is smaller, being $333,063 compared with $478,986 in 1954 and $760,295 in 1953. The welfare agencies support six hospitals, which have a total of 4,029 beds. In 1954, 68,741 patients were hospitalized, or 3,526 more than in 1953. The outpatient consultations have similarily increased from 426,248 in 1953 to 538,687 in 1954. The average cost of maintaining a patient in such hospitals is $1.20, which is much less than the cost per patient in the hospitals supported by the government. This discrepancy cannot be overcome unless larger amounts become available to the welfare agencies.

Treatment of Tuberculosis.—At the postgraduate course given at Arequipa in July, Prof. Orrego Puelma, speaking on the treatment of tuberculosis, said that isoniazid appears to favor cellular metaplasia through direct action on the connective tissue, and, although this may result in complete resorption or fibrosis, it may lead also to an increase in caseation. A combination of streptomycin and isoniazid affords the most reliable treatment, and aminosalicylic acid is recommended only for patients in the acute stages and in the treatment of tuberculous meningitis. Much better results were obtained in the treatment of tuberculous bronchitis by giving oxytetracycline with streptomycin than with streptomycin alone or in combination with any other known antituberculous agent. Large doses of vitamin C and the vitamin B complex constitute a valuable adjunct to treatment.

Hypertension.—At the same postgraduate course, Prof. Rojas Villegas said that a combination of pentolinium tartrate with Rauwolfia serpentina is the safest and most effective method of treating hypertension and that even malignant hypertension sometimes yields spectacularly to this therapy. The average daily dose of pentolinium tartrate used was 140 mg. and of reserpine, 8 mg.

Hospital Administration.—An inter-American seminar on hospital administration, organized under the auspices of the American Hospital Association and the Inter-American Hospital Association in collaboration with the most important Peruvian medical, social, and public welfare agencies, was held in Lima in July. The failure of the nonfederal hospitals to gain the approval of the Inter-American Hospital Association is primarily due to their lack of funds. Of about 16,000 beds available in all the hospitals of Lima, 4,027 are in these nonfederal hospitals. Although their support has increased in recent years, the care of the patient is still inadequate more often than not, and the clinical records are incomplete. This is particularly unfortunate in view of the fact that many of these are teaching hospitals. Although the standards in the federally supported hospitals are much higher, the Worker's Hospital of Lima is the only one that has gained the approval of the Inter-American Hospital Association.

Psychiatric Campaign.—At the Second Peruvian Psychiatric Journeys held in Trujillo in July, the general lack of psychiatric services outside of Lima was again deplored. Help from the government and private institutions has been almost nil, but it is hoped that the government will initiate an active program soon.

SWEDEN

Use and Abuse of Medical Certificates.—According to one of the statutes of the Swedish Medical Association, the physician who issues a medical certificate must confine himself to his own observations and must also safeguard his patient's interests. This ruling has acquired exceptional significance in the light of recent events connected with a movement by the police of Stockholm and Gothenburg for more pay. On the evening of June 22, the head of the police in Stockholm announced that about 250 policemen had declared themselves unfit for service on account of illness. Next morning the number of policemen in Stockholm on the sick list had risen to about 450, and by the evening of June 23 about 700 policemen, or practically all the policemen required for traffic regulation, had been reported as sick. The same malaise overtook about 100 policemen in Gothenburg. The Minister for Internal Affairs reacted by calling up policemen from other parts of Sweden and making arrangements for drafting them to Stockholm and Gothenburg. He remarked that neither of these towns had been struck by any great wave of illness involving other members of the community and that the higher officers in the police force and the members of its criminal service had been comparatively exempt from illness. For these and other reasons he suspected that the sudden crop of medical certificates of ill health was the outcome of an organized action directed against an important function of the community. Because such action could not be tolerated, he appointed a commission of inquiry composed of three members, one of whom was a high-ranking physician attached to the Sabbatsberg Hospital in Stockholm. In *Svenska läkartidningen* for July 8, it was pointed out that between June 18 and 27 a total of 448 policemen in Stockholm were certified by 92 physicians as suffering from some illness or other. It was also remarked guardedly that it was impossible to say to what extent these physicians may have erred. The answer to this question must wait till the commission of enquiry has published its findings.

Teaching Pathology in the United States and Sweden.—In the fall of 1954 a study of the teaching of pathology at nine medical schools in the United States was undertaken by Dr. Nils Ringertz of the Sabbatsberg Hospital in Stockholm. He found that in eight of these schools teaching was based on the same main principles, whereas the ninth school (Western Reserve University in Cleveland) represented a bold experiment on new lines. His report on this study in *Nordisk medicin* for June 17 tells what the American student does to master the elements of pathology, what examinations he has to pass, and what textbooks he reads. The author also shows in which respects the United States and Sweden differ most in the teaching of pathology. Difficulties over the prompt undertaking of postmortem examinations in the United States are a handicap to the teacher. The typical American student assists in a comparatively small number of autopsies, and his study of isolated, prepared organs is a poor substitute for the complete autopsy. It is, in the opinion of Ringertz, a pity that most experienced pathologists in the United States seldom teach by the autopsy table. On the other hand, keen appreciation is expressed of the United States teaching of pathology in general, and it is noted that more hours are devoted to this subject in the United States than in Sweden. In a table dealing with four Swedish and three American schools (Cincinnati, Harvard, and Cornell), the author shows how much better off the American student is with regard to the number of his teachers, with one teacher to every four students at Harvard and one to eight in Uppsala. Yet when the Swedish student has completed his course in pathology, Ringertz believes he is endowed with more clinical experience and a greater capacity to correlate pathological with clinical findings than his counterpart in the United States.

Thallium Poisoning.—Fairly extensive use is made in Sweden of thallium as a rodenticide. At the department for industrial diseases of the Karolinska Hospital in Stockholm, four cases of thallium poisoning have recently been investigated by Glömme and Sjöström, who point out in *Svenska läkartidningen* for June 3 that thallium poisoning is apt to be overlooked by physicians if they do not inquire into the occupations of their patients because the symptoms may be of a general character. One of their patients was a woman, aged 48, who complained of tingling in the tips of her fingers, the soles of her feet, and her toes without presenting any definite manifestation of polyneuritis. Her complaints might have been dismissed as due to the menopause had not thallium been found in her urine and had not a careful inquiry revealed that the intensity of her symptoms had fluctuated with the degree of exposure to thallium. In this and in the other three cases the thallium sulfate had been handled partly in the dry state and partly as a solution for the impregnation of wheat. Makers of rat poison have hitherto been careless in the handling of thallium with their bare hands, and it is probable that when the necessary precautions are taken and the spilling of a thallium solution on skin and clothes is avoided, this form of industrial poisoning will be eliminated.

SWITZERLAND

A Rare Peromelus.—At the annual meeting of the Swiss Pediatric Society, H. Käser described a female infant in whom, instead of normally developed limbs, there were only stumps with no distal parts. At the age of 1 year the child had conical stumps 11 cm. long in lieu of arms and cylindrical stumps 4 cm. long instead of legs. The somatic and psychic development was otherwise completely normal. Radiograms of the upper extremities showed humeri minus the distal articular segment. The lower extremities had a bone formation that was almost triangular. This case, like those reported in the literature, does not clarify whether the defect is in the parents' genes or is caused by chemical or physical influences, disease of the mother, or a dietary deficiency. It can only be said that the condition is a malformation by inhibition and not a mutilation from intra-amniotic processes; this is shown by the symmetry and lack of scars. Embryologic considerations suggest that the teratogenic period is at the beginning of the second month of fetal life, at the time when differentiation of the extremities takes place.

Pitressin Test.—At the same meeting, Vest of Basel suggested that the commonly used Volhardt thirst test of urinary concentration could be replaced in children by a Pitressin test, which has the advantage of requiring no deficiency in liquids or foods. He practiced both tests in 47 infants and children whose ages ranged from 5 days to 13.5 years and compared the highest specific gravities obtained. The quantities of Pitressin used varied according to the age of the subject (from 1 to 10 units). In general, no significant differences could be found between the two tests in regard to the specific gravity of the urine, although the figures obtained from the Pitressin test were usually a little lower than those of the Volhardt test and varied more widely from the mean value. This is not true of infants less than 3 months old, since they normally have urinary hypotonia. After both tests there was distinct elevation of the specific gravity, but it was less after injection of the hormone. With neither of these tests were values obtained that were as high as those in older children. Thus the Pitressin test can be used in children for examination of the renal function except in young infants, in whom the kidneys' capacity for concentration is as yet insufficiently developed.

Tuberculosis.—Although in the last 50 years the mortality from tuberculosis in Switzerland has greatly diminished, the same is not true for the incidence of the disease. According to Press, there is a morbidity of 1.1 to 1.5% from open tuberculosis in adults, while the morbidity from tuberculosis as a whole has consistently exceeded 4.9%. Ott has pointed out the disproportion between the rapid decrease in mortality from tuberculosis and the constancy of the number of patients with the disease. Switzerland has made a great effort to attack the sources of the infection. Prophylaxis is directed toward prevention of infection, increase in defensive forces, and protection of the organism by BCG vaccination. In 1923, Adler and Loeffler first suggested that large groups of persons be examined by means of serial roentgenograms. This examination is usually practiced today in the form of radiograms made in various large groups and, eventually, among the contacts of patients with known tuberculosis. The effect of this method is clearly shown in the results of a test carried out in the Zürcher Oberland, a region that is both agricultural and industrial. In the 1946-1947 campaign radiography revealed 600 cases of tuberculosis among 46,832 persons examined; 50% of these were unsuspected. In the 1949-1950 campaign 471 cases were discovered in 37,629 persons examined; 54% of them were unsuspected.

The decrease in mortality is due not only to the progress made in medicine but also to improvements in the standard of living. Diet has been better adapted to the needs of the organism, and housing conditions have become more healthful. The reduction of working hours and consequent normalization of the work-rest ratio have contributed to this improvement. Finally, thanks to a way of living that incorporates more sun and light, persons have acquired more physical resistance. The physicians of the Scandinavian countries are to be credited with the institution of BCG vaccination on a large scale. This program was introduced in Switzerland and is now an integral part of antituberculous prophylaxis. In some cantons, realization of the program has been made possible through close cooperation between the medical profession and the Antituberculous League. For example, in the canton of Zurich mass vaccinations are performed every four or five years and mass roentgenography every three years. Periodic vaccination is necessary because of the limited duration of the protection afforded by the vaccine. BCG vaccination is voluntary and furnished gratis. During the period from 1950 to 1953, 91,500 residents of the canton of Zurich were tested with tuberculin; 53,300 in whom there was a negative reaction had been vaccinated with BCG. After a period of controversy, the Swiss medical profession decided in favor of the vaccine. Recently the city of Geneva opened its vaccination center. Considering the epidemiological conditions prevailing in Switzerland now, vaccination would seem to be indicated in adolescence. BCG vaccine will be administered in the higher classes of elementary school so that the young people can be fortified against the time when they will enter the atmosphere of factory and shop, where the risk of infection is great compared with that in the protected atmosphere of school and family. Vaccination will be offered to young men entering military service. The physician-in-chief of the Army has asked that the recruits be vaccinated before the start of basic training. Vaccination is essential for the following groups of the population: hospital personnel; medical students; children, adolescents, or young adults from tuberculous environments; and other groups particularly threatened with the disease. It would be desirable for all students and apprentices to be protected, but these are difficult groups to reach. BCG must never be imposed on the population but must always be offered on a voluntary basis.

The drop in tuberculosis mortality of the last 10 years has been mainly the result of the use of antituberculous medicaments. Patients with tuberculous meningitis, pulmonary tuberculosis, and tuberculous disease of the mucous membranes, bones, and kidneys are especially benefited by these agents. The concept of the tuberculous phenomenon has been completely revised. The old methods of treatment have been almost entirely abandoned in favor of resection, which has the advantage of eliminating the diseased portions from the body. In Switzerland, resection has superseded pneumothorax, both intrapleural and extrapleural as well as thoracoplasty and plombage. Switzerland's mountain sanatoriums are now assuming more and more the function of hospitals, rather than that of convalescent homes as they were originally. Diagnosis and therapy demand specialized equipment and the services of a specialized surgeon. Most sanatoriums are acquiring these things and managing to weather the financial strain involved, but some have had to close their annexes. There is also a certain trend away from these institutions. Treatment at home has been greatly facilitated and probably also abused to some extent.

Small Hole in the Iron Curtain.—For the first time since 1945 the Polish government has allowed a Polish physician to study in Switzerland. Dr. Nyklewicz, director of the Bialystok (Poland) Hospital and head of the Clinic of Gynecology and Obstetrics, is now studying at the University of Geneva. It was in 1954, at the International Congress of Gynecology and Obstetrics held in Geneva, that a member of the Polish delegation started negotiations for this trip.

MISCELLANY

SMOKE ABATEMENT

Richard Gordon

Reprinted with permission from Punch, *Feb. 24, 1954.*—Ed.

Smoking has a particularly strong appeal to the British public because it is our only vice which is wholly respectable. Clergymen puff away blamelessly, in life and in advertisement; schoolmasters bathe their corrected exercises in rich blue clouds; dons traditionally pickle their undergraduates with latakia. Nothing creates an appearance of thoughtfulness, solidarity, and honesty in the British mind more powerfully than a pipe.

Politicians who would rather defy a Whip than be spied by their constituents holding a glass, pose proudly for photographs with their smoking insignia. What Englishman can picture a safe-cracker pausing at his job to relight his favourite briar? And who thinks the worse of Sherlock Holmes for continuously filling himself with noxious agents by the mighty bowlful?

The discovery of the spoil-sport statisticians that smoking is really a more dangerous pastime than speedway racing has already propelled quiet ripples of confusion through the medical profession. Most doctors smoke, and addicts are poor arbiters of their addiction: while the practitioner who comes mellow from his after-lunch pipe is murmuring in his surgery, "A little of what you fancy . . .", his colleague, white-hot in the fresh fires of abstinence, sends his patients away emptying their cigarette-cases like loaded revolvers.

I gave up smoking myself when I was a medical student, after discovering one afternoon, in the index of Price's *Textbook of the Practice of Medicine,* the entry between Smallpox and Snakebite:

Smoking a cause of chronic pharyngitis
  a cause of ptyalism
  cardiac symptoms of
  excessive, enterospasm in
  harmfulness of, in intestinal spasm
  in relation to atheroma
    to gastric and duodenal ulcer
    to gastric irritation
    to intermittent claudication
    to laryngitis
    to palpitation
    to pulmonary tuberculosis
    to thrombo-angiitis obliterans

This seemed to describe so clearly my condition when groping for the morning cigarette that I instantly gave my daily packet to the mortuary attendant, and decided to discover by private research why other people tolerate these life-long symptoms as cheerfully as a schoolboy's split knees. This is a difficult clinical investigation, because nobody will admit he smokes because he wants to. The reasons most commonly offered in the consulting room for a chronic bronchitis and mahogany fingers are:

Me nerves, Doctor
Sort of helps me to think
Can't digest nothing otherwise
Keeps down the weight
Keeps up the weight
Everyone else does
Habit, I suppose
Keeps the moth out of the carpet.

A search for more precise reasons from my scientific colleagues barely furthered the investigation. A physiologist declared that if you paint the nerves in a cat's neck with a solution of nicotine the animal gives an enormous wink. This, he explained, is why cats don't smoke, but he could go no further. A hospital pharmacologist, who smokes an old pipe bilaterally notched through a lifetime of lighting from Bunsens, explained that a cigarette contained enough nicotine to slaughter an alley-ful of cats, was packed with ammonia and other unpleasant vapours, and gave off more carbon monoxide than an old car. He had no explanation why a queue of men, during the war, were prepared to stand in the rain for half an hour on the off-chance of being permitted to buy a packet of these bundles of poison. A psychiatrist merely murmured darkly about remnants of infantilism, and recommended playing with an abacus after dinner instead. It seems that no smokers can possibly enjoy smoking; they smoke only because they don't enjoy it if they aren't.

This makes the problem of stopping smoking impossibly complicated, and the brave British public will probably continue to puff itself into a premature grave to the dismay of the Ministry of Health and the delight of the Exchequer. The common man has accepted without grace the assurance that the more he smokes the more likely he is to kill himself, for he has a constitutional dislike of statistics and his common sense tells him (1) lots of people smoke heavily and don't get cancer; (2) lots of people get cancer and don't smoke heavily. In the last century his common forbears decided for the same reasons that germs don't give you diseases like typhoid and cholera; but common sense never lacks its martyrs, and their bones form thick memorials to our forgotten centres of insanitation.

Medical science never takes away without giving something in return. In the last ten years it has discovered you can drink as much as you like if you swallow plenty of vitamin B, and your liver won't end up as a lantern slide in a temperance lecture. If everyone smoked less and drank more the Exchequer wouldn't suffer and we should all be healthier. Possibly we would beat our wives a little, but what are a few more bruises and fractures to the National Health Service? This is an unsentimental age.

ROGER GILES, SURGIN

Reprinted with permission from the Chicago Daily Tribune. —Ed.

Skulemaster, Groser and Hundertaker, respectably informs ladys and gentlemen that he drors teef without wateing a minit, and sells vizicks for a penny a peace; Joes-harps, penny wissels, fryin-pans and other moozikal Hinstruments, hat grately reydoosed figers. As time is cruel bad I begs to tell ee that I also teaches yung ladys and gentlemen their grammur in the purtiest mannar and grate care is taken of their morrels and spelling. Halso I sells ginger beer, matches and other pickles such as hepsom salts, hoysters, and winzer sope. I also taches gography, rithmetic, and jimnasticks. Gode Save Thee Kinge.

THE LEISURE CORNER

MEDICAL POETRY

Doctors are writing creatures. Some of them seem to write as naturally as beavers build dams or sea gulls prey upon shellfish, but usually in their spare time. This is only natural due to the fact that physicians from the beginning are trained in writing down case histories, summaries, diagnoses, and prognoses. Perhaps the most universal of all hobbies for all physicians is book-collecting, but writing probably comes next, and each reinforces the other. Every physician has a shelf of books, even if it is only the textbooks he studied when he was in medical school, but nearly every physician has a few volumes that represent his personal choice in reading. Nearly all doctors spend some time reading medical journals, and most spend some time reading general literature. It is not an obsession, it is a natural habit, resulting from the methods of training in modern (and for that matter, in ancient) schools of medicine.

As a special department of this phenomenon, there is the field of poetry that somehow seems remotely connected with music in that poetry is more musical than prose. Doctors also are musicians, but less prominently. It might be remembered here that poetry, music, and medicine were all the special interests of Apollo, sometimes called the "God of Medicine and Poetry." However that may be, doctors see so much and experience so much and do so much that is active, useful, and noteworthy, it seems only natural that they should record what they see, experience, and do in prose or poetic fragments. Some have even achieved more. For example, one of the greatest of all ancient poets was probably a physician. That is to say he was the equivalent of what we consider the scholar-physician today. Actually the word physician means "naturalist" and Lucretius was that, preeminently. His epic poem "Concerning the Nature of Things" covers just about everything medicine, psychiatry, and epidemiology include today. Almost nothing is known about his life, but histories estimate he may have lived between 98 and 55 B. C. There is much speculation about him, his health, and his habits, but his work speaks for him more eloquently than histories could. It is a magnificent achievement, and the many translations starting with that of Dryden give an impressive view of the mentality of the author. Particularly of interest to physicians is the last part of this epic poem that describes graphically a plague that Lucretius had heard about from Thucidides and later documented for himself in Latin verse. He is classed among the Epicurean philosophers, but it is as a poet that he is outstanding.

Many authors believe "Concerning the Nature of Things" by Titus Lucretius Carus to be the third greatest poem in the world, the first two being the Iliad and the Odyssey attributed to Homer. Some authorities claim that Lucretius has drunk deeper of the scientific spirit than any other poet of ancient or modern times except Goethe, who was himself a physician of sorts. That is to say, in his universal quest for knowledge he embraced all he could of contemporary or ancient and medical knowledge. This particular poem "Concerning the Nature of Things" bears all the earmarks of having been written by a man who was clinically observant and medically oriented. It is a profound book that must be read slowly and requires intensive study. So it is that any consideration of medical poetry or poet-physicians must begin with consideration of Titus Lucretius Carus.

After him, the field is very wide and plentifully stocked with poets who were physicians and physicians who were poets of all sorts. A more complete account of this subject may be found in "Poet Physicians," compiled by Mary Lou McDonough and published by Charles C Thomas, Publisher, in 1945. Let us consider Wang Wei, a young country doctor in China who was also a public health officer in his own community. He was probably an herb doctor, as all Chinese medicine was herb medicine in his time (699-759 A. D.), but his paintings and his poems are still counted among the irreplaceable treasures of his homeland. Read in translation today, his poems seem strikingly modern.

Medical students today memorize the cranial nerves by learning the jingle: "On old Olympus' piny tops, a Finn and German vainly ate hops," or some such version of this couplet. This device represents a hangover from a time when a vast amount of medical knowledge was put into rhyme and memorized. "The School of Salerno" is an example. It is a long poem written by one or more authors, probably all members of the faculty of the School of Salerno and as such it is one of the oldest medical poems. Its "Regimen Sanitatis" was written in double-rhymed Latin hexameter about 100 A. D. It was first printed in German in 1472 and later reprinted in Latin and has since been widely quoted. For 500 years almost every physician in Western Europe was thoroughly familiar with this remarkable poem, which assumed of itself a kind of oracular authority.

No list of physician-poets would be complete without mentioning Girolomo Frascatoro. He was indeed a remarkable man and for many reasons. He knew astronomy, philosophy, mathematics, and what geography and botany as was taught at that time (1483-1553), but his crowning achievement is the poem in which he described syphilis precisely, telling about its incidence and course in various countries of Europe. This poem titled "Syphilis Sive Morbus Gallicus" describes the use of a heavy metal (mercury) in the treatment of that disease and contains the germs of many other ideas that later sprouted to full growth in the work of Pasteur, Schaudinn, and Fleming. This poem is a remarkable combination of practical information and symbolic explanation. In the book he tells how a young man infected with syphilis was supposed to have been cured by a goddess who bathed him in a lake of silver in an underground cavern. Psychoanalysts would find delight in that.

There were many physicians who chose poetry as a means for spending their spare time. To mention but a few—Thomas Campion, who was a contemporary of Shakespeare; Abraham Cowley, who came a little later; Henry Vaughn, noted among the metaphysical poets; and John Arbuthnot, who lived during the Golden Age of English literature. Arbuthnot was a Scottish physician. He received his degree as a doctor of medicine at St. Andrews' in Scotland and was appointed Physician Extraordinary to Queen Anne. Mark Akenside (1721-1770) wrote a remarkable thesis on the development of the human fetus and at the same time produced his epic poem "The Pleasures of the Imagination." There are dozens, actually, some known for a single poem, some for one book, and some for a more impressive output, but all sharing the common factor of the medical background and the discipline of medical training.

Few people know that Edward Jenner (1749-1823), who began the world's greatest conquest of disease with the discovery of and the application of vaccination and who was a student and an interne of the great Dr. John Hunter of London, also found time to write poetry. His "Address to a Robin" and "Signs of Rain" are classical examples of poetic art. Then there was Schiller, who completed his medical training at the age of 21 and who was drafted into military service as a regimental surgeon at Stuttgart. His play "The Robbers" and his famous dramas, "William Tell" and "Maid of Orleans" will be remembered as long as the German language lasts. Besides, he was the friend of Goethe and, incidentally, was the son of an Army surgeon.

Mention should also be made of John Keats, who was appointed as a dresser at Guy's Hospital in London in 1816 and in July of the same year passed with credit his examinations as a licentiate at Apothecaries in London because he abandoned surgery, giving as a reason the fact that he felt himself not fitted for it. Tuberculosis mowed him down in 1821 but not before he had written some of the finest poetry in the English language. One might also list Thomas Holly Chivers (1807-1858), who is remembered partly for his association and his controversy with Edgar Allen Poe. Chivers graduated as a doctor of medicine in 1830 from Transylvania University, Lexington, Ky., and was offered a chair in that university 26 years later. For this period, he wrote poetry that was unique. He was also a painter and an inventor. He designed a machine to split the fibers of silk from the cocoons of silkworms.

The crowning achievement of the muse in the 19th century in the United States of America was Dr. Oliver Wendell Holmes, born in 1809, died in 1894. He almost spanned the 19th century. A preeminent physician, he taught at the Harvard Medical School and practiced in Boston. His most famous article was "The Contagiousness of Puerperal Fever," which everyone now takes for granted, but in his day it was a very novel idea. He will always be remembered for "The Autocrat of the Breakfast Table," "Old Ironsides," "The Wonderful One-Horse Shay," and his most distinguished poem "The Chambered Nautilus." No poet writing in England or America has ever produced a single poem of greater distinction and beauty. It embodies a spiritual philosophy based on materialistic observation that even today is incomparable, and rarely indeed does anyone even approach the exalted level of the human utterance this poem expresses.

As for the present century, it is too early to tell who the medical poets are, but certainly preeminent among them is William Carlos Williams, M.D., now three score years and ten and a longtime practitioner in New Jersey. His many volumes will reward the reader who seeks them out. Even at 70, he continues to write with the tongue of youth, which is the tongue of poetry. And also there is Merrill Moore, whose efforts on behalf of the sonnet have been poetically therapeutic and possibly not in vain. Moore is known for his many books, all products of his leisure time. (See "Poet and Psychiatrist" by Merrill Moore, M.D., a clinical portrait with an appraisal of his poems by Henry W. Wells, published by Twayne Publishers in 1955.) He works from nine to five as a practicing psychiatrist in Boston. His books, "The Noise That Time Makes," "Six Sides to a Man," "*M*: One Thousand Autobiographical Sonnets," "Clinical Sonnets," "More Clinical Sonnets," "Illegitimate Sonnets," "Case Record from a Sonnetorium" and "A Doctor's Book of Hours" are works that bear the seal of the physician.

MEDICAL FILM REVIEWS

One Victory: (Cleared for television) 16 mm., color, sound, showing time 10 minutes. Produced in 1954 and procurable on loan or purchase ($75) from University of Minnesota, Audio Visual Education Service, Basement, Wesbrook Hall, Minneapolis 14.

The purpose of this film is to show a case history of a young girl who is given the opportunity of having a normal life through the efforts of the staff and facilities of the University of Minnesota Heart Hospital and to inform the public of what the Variety Club Heart Hospital is doing. The film shows heart specialists and surgeons preparing the 5-year-old girl for surgery to correct a congenital defect inside her heart. Doctors had been experimenting with animals and found that the heart could be tied off from the body's circulation by the help of a refrigeration blanket for as long as 10 minutes and by lowering the body's demand for oxygen from the blood. This is a reenactment of the successful first attempt to use the new technique on a human patient. This is a film prepared for nonmedical use, to stimulate public interest in the Variety Club Heart Hospital at the University of Minnesota, in particular, and in the possibility of successful results from heart surgery in general. Operative techniques are only suggested, and the audience to be reached seems to be those who are apprehensive about having surgery performed on their children. This film could also be used as a presentation of medical progress with emphasis on the value of research. The photography and narration are well done.

Peridural and Caudal Anesthesia: 16 mm., color, sound, showing time 20 minutes. Prepared in 1954 by Charles C. Wycoff, M.D., University of California, San Francisco. Sponsored by Astra Pharmaceutical. Procurable on loan from Charles C. Wycoff, M.D., San Francisco Hospital, San Francisco 10.

This film presents briefly the anatomy and author's technique in peridural and caudal anesthesia. After an abrupt introduction, demonstrations are made on a skeleton of the method of localization of the site and route of insertion of the needle for both peridural and caudal injections. Demonstrations of these two methods of anesthesia are then made on patients. Emphasis is placed mainly upon the mechanics of insertion of the needles, verification of the sites, and injection of the anesthetic solutions. Unfortunately, much of the narration is too rapid and not synchronized with the image on the screen. Complications are narrated, and their management is briefly considered. The importance of having efficient mask oxygen therapy immediately available should be added to this discussion. This film should include emphasis upon the need for strict asepsis as well as the avoidance of the use of irritating solutions. It would be enhanced by the addition of illustrations and discussion of the methods for localizing and controlling the extent of blocks obtained with these procedures. The photography is excellent. In its present form, this film might be of interest to advanced residents in anesthesiology and qualified anesthesiologists.

Mrs. Hazard's House: 16 mm., color, sound, showing time 13 minutes. Produced in 1954 by King Horton Productions, Los Angeles, for and procurable on loan or purchase ($79.20) from Prudential Insurance Company of America, 5757 Wilshire Blvd., Los Angeles.

The purpose of this film is to educate parents on the need for practicing and teaching safety habits to their children in an effort to help prevent child accidents in the home area. It opens with an animated portion that shows "Mrs. Hazard's House" and many of the hazards that exist in the home area. It is revealed that the animated portion has been a telecast, and a young family group is shown watching this telecast. They comment on the hazards that have been demonstrated and assure each other that no such hazards exist in their home. At this point, the announcer on the telecast speaks to them cautioning that it might be a good idea to look around their home more carefully and suggesting a few places they might check. In the following sequences they check some of these points and find that there are potential danger points for their child. The film closes with the author speaking on the general subject of child accidents. This film is very well done, in particular the parts that graphically present the hazards to be found in the home. This film is recommended for parent groups and classes for prospective parents.

Congenital Absence of the Vagina and Its Treatment: 16 mm., color, sound, showing time 24 minutes. Prepared by Joseph Gaster, M.D., College of Medical Evangelists, Los Angeles. Produced in 1954 by College of Medical Evangelists and procurable on loan or purchase from Joseph Gaster, M.D., 416 N. Bedford Dr., Beverly Hills, Calif.

This film presents an interesting and educational exposition of a relatively uncommon condition. The technique demonstrated is somewhat more extensive than that in common usage but, as employed by the demonstrator, serves the purpose very well. The two cases presented are ideal from a standpoint of showing the problem and end-results. As shown in the film, the creation of an artificial vagina utilizes sharp, blunt section of the genital space and epithelization by means of a split thickness graft over a Pyrex form. There is excellent demonstration of the internal appearances. The photography is also excellent, and there is good continuity with a minimum of extraneous or nonessential footage.

NEW FILM ADDED TO A. M. A. MOTION PICTURE LIBRARY

Streamline Flow in the Veins: 16 mm., color, sound, showing time 10 minutes. Demonstrated by Dr. D. A. McDonald and Dr. E. P. W. Helps, the Medical College, St. Bartholomews Hospital, London. Produced in 1954 by the Wellcome Film Unit, London. Procurable on loan (service charge $2) from Committee on Motion Pictures and Medical Television, American Medical Association, 535 N. Dearborn Street, Chicago 10.

In this film streamlined and turbulent flow are demonstrated in a glass model. Reynold's formula, giving the critical conditions for the change from one type of flow to another, is discussed. By means of dye injected into tributary veins, the type of flow at different points in the rabbit's vena cava and portal venous system is observed. Two practical applications are brought out in this film: (1) the fact that incomplete mixing of the blood in enlarged veins means that samples drawn by needle are sometimes not representative of the total content of the vein; and (2) that localized infections in such organs as the liver can result from the movement of infected material through veins with incomplete mixing. This film will be of great interest to physiologists specializing in the field of circulation, and, since the phenomena it demonstrates are not easily exhibited in the laboratory, it should prove to be of value in courses of physiology for medical students. The authors deserve a compliment for the care with which the materials have been arranged for photographing.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Rheumatic Heart Disease in Scarlet-Fever Patients Treated with Penicillin: A Follow-Up Study After Seven Years. L. Weinstein, N. H. Boyer and M. Goldfield. New England J. Med. **253:**1-7 (July 7) 1955 [Boston].

The authors report observations on patients examined seven years after they had been treated with penicillin for scarlet fever. To provide a basis for the proper evaluation of the observations made in 1953, results of the studies carried out in 1946 are briefly summarized. One hundred sixty-seven patients with scarlet fever were treated by intramuscular injection of 15,000 units of penicillin every three hours for 10 days. Group A Streptococcus pyogenes was isolated in every case at the time of hospitalization. The majority of the patients were 2 to 15 years of age. Electrocardiograms were obtained daily in most patients and every other day in a few. The patients remained in the hospital for a minimum of three weeks, some for longer periods. In 12 of the 167 patients acute rheumatic fever was thought to have developed despite the use of penicillin. One hundred ten of the 167 patients treated in 1946 returned for study in 1953. Of these, 100 had had normal or borderline electrocardiograms, with no clinical manifestations of the rheumatic state, and 10 had been suspected of having had rheumatic fever seven years earlier. None of those without electrocardiographic changes in 1946 had any evidence of cardiac disease in 1953. Of those with prolonged PR and QT intervals seven years earlier eight had definite or "probable" rheumatic heart disease. In six mitral insufficiency and stenosis were present; two of these had aortic as well as mitral lesions. The data presented suggest that penicillin therapy of streptococcic pharyngitis in children, even when applied early, may not significantly decrease the occurrence of acute rheumatic carditis. In children the clinical features of the acute rheumatic state may be markedly suppressed by the chemotherapy of the initiating streptococcic infection so that most or all of the characteristic signs and symptoms are absent and electrocardiographic evidence of carditis becomes the most prominent and sometimes the only diagnostic feature. Because of this it is probably necessary to redefine the present criteria for the diagnosis of acute rheumatic fever, particularly for children with antibiotic-treated streptococcic pharyngitis. Demonstration of prolonged atrioventricular-conduction time, after a latent period, probably is highly significant for the diagnosis of rheumatic carditis in the absence of major manifestations, if the patient can be proved to have had a recent streptococcic infection.

Premonitory Period of Myocardial Infarction. P. Maurice, J.-L. Beaumont, A. Leupin and J. Lenègre. Arch. mal. cœur **48:**551-566 (June) 1955 (In French) [Paris, France].

The authors studied 108 patients with myocardial infarcts and found that 60.2% of them had had the classic form of attack with no premonitory symptoms. This group was fairly evenly divided between those patients in whom the infarction was the first clinical sign of coronary disease and those with long-standing angina pectoris. In 43 patients (39.8%) of the series, there existed a premonitory period the duration of which varied from a few hours to over a month (average 17.1 days). The period was characterized by the appearance or aggravation of angina. There was no fever or leukocytosis and the erythrocyte sedimentation rate was unchanged. Having recognized the premonitory period of myocardial infarction as a clinical entity, the authors made a thorough study of 71 patients with angina pectoris whose usual pattern of pain was undergoing change. No clinical criteria could be set up for determining whether their disease would progress to myocardial infarction or not, but electrocardiography frequently showed anomalies that reinforced clinical suspicion. These disturbances were usually those of acute or subacute coronary insufficiency. In 39 of 62 patients there was an ischemic lesion, subendocardial in 15 and subepicardial in 24; in 20 of the 62 there was an isolated subepicardial ischemia. These anomalies are significant only when their recent appearance can be proved (by comparison with previous electrocardiograms). The finding, in three patients, of a blood hypercoagulability in the days preceding necrosis led the authors to look for such a warning sign in the other patients. Intense or moderate hypercoagulability, as manifested by the in vitro resistance to heparin, was found to be immediate in 49 patients (69%) and secondary in 15 (21%); the authors believe it to be a factor of extreme importance, since it is not ordinarily present in severe angina and may therefore act as a diagnostic indication of impending coronary attack. The 71 patients were given anticoagulant therapy with various agents. Pain disappeared in 64.4% of them, was clearly benefited in 29.5%, was unchanged in 2.8%, and was aggravated in 2.8%. It would seem that treatment with anticoagulants is particularly necessary in, and beneficial to, patients with recent alterations of an established pattern of angina pectoris.

Is Phenylethylacetic Acid Antiatherogenous? J. Cottet and A. Mathivat. Presse méd. **63:**1005-1007 (July 2) 1955 (In French) [Paris, France].

Phenylethylacetic acid has a definite antiatherogenous effect in experimental animals. The authors used phenylethylacetamide (hyposterol) in the treatment of 37 patients with atheromatous cardiovascular disease over a period of from one to six months. It was found that the drug has an effect on the total serum lipids. Cholesteremia was decreased in 75 to 80% of the patients, and this effect was more marked as the amount of blood cholesterol was higher to begin with. The decrease was generally statistically significant and sometimes reached 40 to 50%, even 60%. Normal rates of cholesteremia were not affected. In one-fourth of the patients a transitory rise in blood cholesterol was observed between the fourth and eighth weeks of treatment; this was usually followed by a fall to levels below those seen before treatment. The phenol turbidity reaction of Kunkel was decreased as much as 50%. Lipemia was affected in about the same way as cholesteremia. Lipid fractionation at electrophoresis was modified by hyposterol, with a tendency toward normalization of the profile. It is thus concluded that phenylethylacetic acid acts on the biochemical disturbances that characterize atherosclerosis, tending to restore the organism to normal.

Mitral Disease and Epileptic Syndrome. G. B. Lusiani and G. P. Vecchi. Minerva cardioangiol. **3:**217-223 (May) 1955 (In Italian) [Turin, Italy].

The authors report the histories of five patients with mitral disease, mainly mitral stenosis, in whom a first epileptic attack occurred in adult life and suggested the presence of a relationship between the two conditions. The convulsive attacks with loss of consciousness were true epileptic seizures and not syncopal manifestations with convulsions. Little is known about the mechanism of dependence of epilepsy on mitral disease; many pathogenetic hypotheses have been advanced, but none gives a satisfactory explanation. The authors state that a latent epileptogenous focus might occasionally be disclosed by a hemo-

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1946 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

dynamic circulatory disorder. Therefore, the condition sine qua non present in these patients before heart disease was, according to the authors, a latent epileptogenous condition, which became clinically evident after a long interruption of the strong systolic contractions followed by acute cerebral ischemia.

Differential Diagnosis Between Bronchial Carcinoma and Unspecific Pneumonia. V. Kesztele. Wien. med. Wchnschr. **105:** 514-516 (June 25) 1955 (In German) [Vienna, Austria].

Seven men between the ages of 40 and 67 are reported on in whom differential diagnosis between unspecific pneumonia, which they had, and bronchial carcinoma, which was suspected, was clarified only by surgical intervention. The subjective complaints of the patients corresponded with those of almost any disease in the thoracic cavity and were of little value with regard to evaluation. There was relatively little irritation causing cough and only moderate expectoration in patients with abscess formation and bronchiectatic cavities. The lancinating pain in the chest and back was most pronounced in the patients with a middle lobe syndrome, and it was somewhat less intense in those with desquamative pneumonia. The involvement of the surrounding pleura played a decisive part in this pain. Patients with desquamative pneumonia of one year's duration associated with abscess formation had the greatest loss in body weight, i. e., 33 lb. (15 kg.), while patients with carnification pneumonia lost 22 lb. (10 kg.) in the course of five months. The duration of the disease varied from six weeks to one year and despite unsatisfactory results from conservative treatment supplementary tests were omitted. Signs of infiltration and disintegration lent themselves to interpretation in the sense of tuberculosis as well as of other parenchymatous diseases, while laboratory and cytological findings proved the absence of tuberculosis in most patients, particularly in those with carnification pneumonia. A malignant condition could not be proved or excluded. Horizontal and transverse tomographic examination supported the suspicion of tumor in five patients. In two patients with interstitial and chronic pneumonia the tomograms were not suggestive of tumor, but in both these patients bronchial narrowing or occlusion was shown by bronchography and bronchoscopy. Bronchoscopic findings were significant in revealing purulent secretion in the patients with abscess formation and suppurative bronchitis. In the other patients, they only showed redness of the bronchial mucosa, and in one patient with desquamative pneumonia, bronchoscopy revealed narrowing of the bronchus, as did bronchography also. All patients had been treated with antibiotics and some of them with sulfonamide compounds and tuberculostatics, but without any improvement in the patients' condition. After exclusion of infarction pneumonia and tuberculosis, surgical intervention seemed indispensable because of the roentgenologically and bronchographically supported suspicion of tumor. Except for one patient with far advanced desquamative pneumonia who died of postoperative hemorrhage caused by erosion and of pulmonary gangrene, the other six patients recovered. Although the most modern diagnostic methods may have their limitations, it would be wrong not to make use of them. The author's cases were reported in an attempt to convince the physician of the necessity of making supplementary studies.

Significance of Tobacco Smoking and Other External Factors in Origin of Pulmonary Cancer. N. Ringertz. Nord. med. 53:951-956 (June 16) 1955 (In Swedish) [Stockholm, Sweden].

The increased frequency of cancer of the lung has brought a change in the relative frequency of the different histological types of the disease. Pulmonary cancer in women has not increased in proportion to that in men. Pulmonary adenocarcinomas, which by and large maintain an even sex apportionment, are assumed to make up the main part of pulmonary cancers on an endogenic basis. The increased incidence of pulmonary cancer is ascribed to increased influence of exogenic factors that act more intensively or have been able to act longer on men than on women. The chief causes are sought in the intensified exposure of large numbers of persons, especially in industrial areas, to carcinogenic substances suspended in the air in more or less closed places of work and in exposure to tobacco smoke. Some parallelism is demonstrable between cigaret smoking and the incidence of cancer of the lung after 15 or 20 years, and the numerous comparative investigations of the smoking habits of patients with the disease and of the control series show consistent results. Experimental evidence for correlation between tobacco smoking and pulmonary cancer is less strong than the statistical evidence. If the increasing incidence is to be arrested on a long-term basis, a campaign must be instituted against heavy smoking, particularly the cigaret smoking of young persons, and measures must be taken to reduce carcinogenic pollution of all places of work and to promote further research for the identification of carcinogenic substances in tobacco. Investigations during recent years testify to carcinogen in tobacco smoke, although in low concentration. Experimental studies are directed to the establishment of the amount and kind of carcinogenic substances in tobacco and its combustion products. The chemical composition of these carcinogens is not yet known. The fact that high combustion temperature is needed for the smoke to contain carcinogens may perhaps afford an explanation of why according to statistics cigaret smoking is more dangerous than pipe or cigar smoking.

Practical Data on Personal Experiment with Trypsin Aerosol Therapy: Report of 312 Patients. A. Biron and L. Choay. Presse méd. 63:1007-1008 (July 2) 1955 (In French) [Paris, France].

Three hundred twelve nontuberculous patients with bronchiectasis, acute atelectasis, and bronchial asthma, complicated in some cases by infectious bronchitis, were given aerosol therapy with trypsin. Results were excellent in 236 patients, good in 11, and unsatisfactory or nonexistent in 65. The patients received half-hour sessions of therapy morning and evening; relief was ordinarily obtained within two days, but some patients had to have as many as 20 sessions of therapy. It is possible to associate antibiotic therapy with this method, but no significant gain is made thereby. A bronchodilating agent is a useful adjunct; the authors used aleudrine (isoprenaline 1%). In the dose used (0.25 gm. a day), trypsin had no effect on blood coagulation. The presence of expectoration that must be liquefied is the indispensable indication for trypsin therapy. When this rule is followed, there are few side-effects of therapy. True tracheobronchial intolerance of the product is rarely encountered, and skin or mucosal reactions are easily controlled with antihistamines. Nebulization therapy should not be used on young infants. Trypsin in aerosol is an efficient therapy for pulmonary disorders in which there is hypersecretion.

Diphtheria Morbidity and Antitoxic Diphtheria Immunity with Regard to Anatoxin Vaccination. E. Tosi. Riv. clin. pediat. 55:166-189 (Feb.) 1955 (In Italian) [Florence, Italy].

An investigation was carried out to ascertain the causes of the high diphtheria morbidity in Italy despite the enforcement of a law making antidiphtheritic vaccination compulsory for all children in the 2nd year of life. A study of 1,100 children attending the Pisa public schools revealed that the disease attacked mainly children of the school age group (6 to 14 years) regardless of whether they had or had not received the vaccination in the 2nd year of life. It thus revealed that the vaccination carried out according to Italian laws on active prophylaxis against diphtheria does not protect the child of the school age group from the infection. A study of children who had been vaccinated indicated that the immunization conferred on the child by the first vaccination lasts for an average of one year and that children of the school age group are practically without any defense against the disease at a time in which the possibilities of contagion are greatest. The degree of vaccine immunization can be increased and the period of its duration prolonged up to the preschool age if, one year after the first vaccination, a new dose of vaccine (recall injection) is given. If immunization is tó be prolonged for the entire school period, it is necessary to give a second recall injection at the time the child enters school (6 years of age). The author advocates the passing of a law that will make compulsory the administration of recall injections, at least two of them, to children in 3rd and 6th year of life.

Prolonged Antibiotic Therapy of Pulmonary Tuberculosis with Isoniazid Associated with Streptomycin or *p*-Aminosalicylic Acid: Its Influence on Indications for Pneumothorax. P. Véran. Semaine hôp. Paris **31**:2354-2359 (July 2) 1955 (In French) [Paris, France].

A comparison is made of the results obtained over a 10 month period in two similar groups of patients with ulceronodular tuberculosis, one treated with isoniazid and streptomycin and the other with isoniazid and *p*-aminosalicylic acid. The first group numbered 87 patients at 2 months but dwindled to 51 at 10 months. The second group had 78 patients at 2 months and 50 at 10 months. Expectoration was more often dried up by isoniazid and streptomycin than by the other combination. The results were radiologically the same for both methods in regard to new lesions and regardless of the extent of the lesions. For old lesions, isoniazid and streptomycin had the advantage. Improvement frequently slowed or stopped at a period characteristically beginning in the fifth or sixth month of treatment. Bacteriologically, the percentage of sputum conversion was slightly higher with isoniazid and *p*-aminosalicylic acid. After a year, some patients still harbored tubercle bacilli, some of which were sensitive and others resistant to isoniazid and most of which were sensitive to streptomycin. The lesions usually remained stationary. Bacterial resistance to isoniazid developed belatedly but in the same manner for both groups. The failure of these associations to benefit cavitary tuberculosis is an excellent indication for pneumothorax, which should not be put off unduly.

Calamities from the Use of Cortisone in Unrecognized Tuberculosis. W. H. Oatway Jr. and G. A. Paulsen. Arizona Med. **12**:275-276 (July) 1955 [Phoenix, Ariz.].

Oatway and Paulsen emphasize that pulmonary tuberculosis can develop after the corticoid drugs have been given for conditions of the joints, skin, and lungs in persons considered (but not proved) to have normal lungs. The seven patients presented by them had received courses of steroid drugs in such a relationship to the onset of their tuberculosis that they can be presumed to have been an eliciting factor. Steroid therapy had been given for arthritis, rhizomelic spondylitis, dermatitis, asthma, and bursitis. In none of these patients had pulmonary tuberculosis been excluded by roentgenoscopy, although two of the patients had a history of earlier tuberculosis. Active tuberculosis was found in the weeks or months after cortisone and other steroid drugs had been used. The patients probably were infectious between the activation of their lesion and the diagnosis of tuberculosis. The authors suggest that the following precautions be taken in the use of cortisone, corticotropin, and other steroid drugs. 1. A pulmonary tuberculous lesion should be ruled out by x-ray examination of the chest. 2. If the x-ray film indicates an inactive lesion, and the use of corticoids proves necessary, chemotherapy for tuberculosis should be added as a precaution. 3. Chemotherapy for tuberculosis may be used if the tuberculin skin-test is positive and a family history of tuberculosis is present. The relative risk in using the steroids in the presence of a probably tuberculous lesion, or even of a positive skin-test, is not certain at present, but it would seem wise to minimize it by a protective blanket of antituberculous drugs. Experiments in animals have shown that tuberculosis is not aggravated and the animal may do well, if antituberculous drugs are used with the steroid drugs. The authors have used cortisone in tiny but effective doses for allergic skin lesions, severe herpes of the face, and similar conditions without harm to the tuberculous lung lesions undergoing chemotherapy.

Analysis of 177 Cases of Hypertensive Vascular Disease with Papilledema: One Hundred Twenty-Six Patients Treated with Rice Diet. B. Newborg and W. Kempner. Am. J. Med. **19**:33-47 (July) 1955 [New York].

In 177 patients with hypertensive vascular disease and papilledema who were admitted to the department of medicine of Duke University in Durham, N. C., between 1942 and 1953, an attempt was made to treat all of them with the rice diet. Follow-up in six patients was inadequate or the treatment period was too short for evaluation. In 33 patients with hypertensive neuroretinopathy treated with the rice diet, electrolyte imbalance developed within the first three months of the diet. Treatment with drastic salt restriction, therefore, could not be carried out, and additional sodium chloride or other chloride was given. In 31 of these 33 patients the total phenolsulfonphthalein excretion in two hours was below 36% indicating impaired renal function. All 33 patients died. Treatment with the rice diet in 18 patients was not carried out at any time; only one of these is still living. In 120 patients with hypertensive neuroretinopathy confirmed by eyeground photographs, treatment with the rice diet was carried out for 1 to 117 months; in 83 of these the total phenolsulfonphthalein excretion in two hours was below 55%; this includes 4 patients in the terminal stage of the disease, in whom the phenolsulfonphthalein excretion was not measured. Forty-seven (57%) of the 83 patients survived one year; 26 (31%) are still living four years and three months (average) after treatment was started. In 37 of the 120 patients the total phenolsulfonphthalein excretion was 56% or more in two hours; 34 (92%) of them survived one year; 26 (70%) are still living five years (average) after treatment was started. One hundred of the 120 patients were followed after the initial period of the treatment with the rice diet, and in these patients the relation of the length of time of supervised treatment to the survival time was studied. In 39 of these patients the period of supervised treatment was 2 to 12 months. Seven of the 39 died during this period while presumably still following the diet; only 3 of the 7 were following it correctly. Thirty-two of the 39 were treated for 2 to 12 months and then to a greater or lesser extent discontinued the treatment; only 6 (19%) of the 32 are still living. Eighteen of the 100 patients were treated for an average period of three years and then to a greater or lesser extent discontinued the treatment. Nine of these 18 patients are still living. The remaining 43 of the 100 patients were treated over one year with the rice diet and continued treatment. Thirty-seven (86%) of these are still living; of the 6 who died only 3 were following the diet correctly. In 92 of the 100 patients in whom the effect of the rice diet on retinopathy was studied with the aid of the available eyeground photographs, papilledema disappeared completely. The effects of the rice diet on blood pressure, serum cholesterol, blood nonprotein nitrogen, T_1 deflection in the electrocardiogram, cardiothoracic ratio, and renal function were studied in 61 patients who were reexamined at least one year after treatment had been started. A comparison of the findings before treatment, during the period of strictest adherence to the rice diet, and at the most recent examination showed that the strictest adherence to the rice diet produced the most favorable results. Dietary modifications, therefore, should be made gradually and with careful observations of blood pressure readings, blood chemical findings, electrocardiograms, chest roentgenograms, and eyeground photographs. Intensive dietary treatment should be started as early as possible and continued until all signs of the vascular disease have disappeared.

The Night-Eating Syndrome: A Pattern of Food Intake Among Certain Obese Patients. A. J. Stunkard, W. J. Grace and H. G. Wolff. Am. J. Med. **19**:78-86 (July) 1955 [New York].

Of 25 obese patients between the ages of 18 and 56 years who were observed at a special study clinic of the New York Hospital, the eating patterns of 20 formed a distinctive syndrome characterized by nocturnal hyperphagia, insomnia, and morning anorexia. Such a pattern was not found in any of 38 persons (graduate and student nurses) without history of weight disorder. This night-eating syndrome was particularly prominent during periods of weight gain and life stress. An effective reducing regimen was not possible in its presence, and it appeared to be intimately related to the pathogenesis of obesity. Of the 20 patients reporting the syndrome only 2 were able to lose more than one-third of their initial excess weight, and in the past only 11 had ever succeeded in losing more than one-third of their excess weight. In 8 of these 11 patients this weight loss was accompanied by disabling emotional illness; only 3 achieved this without disabling complications. Of the five patients not reporting the syndrome, four had carried out successful weight reduction programs in the past. The cases of 2 of the 20 patients are reported in detail, illustrating various aspects of the night-eating syndrome. In the first, that of a 43-year-old single woman, prolonged dietary restriction leading to a marked weight loss did not abolish the syndrome or prevent its intensification in a situation of life stress. In the second patient, a 29-year-old housewife, remission and exacerbation of the night-eating syndrome followed promptly on changes in her life situation and were associated with marked variation in the success of a dietary regimen. The cause of the night-eating syndrome has not been determined. Its characteristics do not reveal whether the mechanisms involved in its pathogenesis are primarily physiological or psychological. It is suggested that the syndrome represents a response to stress of a type peculiar to certain obese patients and that it is intimately related to the pathogenesis of their obesity.

Psittacosis (Ornithosis). O. Heggø and L. Kornstad. Tidsskr. norske lægefor. 75:414-415 (June 1) 1955 (In Norwegian) [Oslo, Norway].

The case of psittacosis (ornithosis) described in a man, aged 48, infected from a sick parakeet, is believed to be the first instance of psittacosis to be reported from Norway. Treatment with Terramycin early in the course was effective, but the dosage was too low and more especially the treatment was terminated too soon, so that there was recurrence. Tetracycline (Achromycin) treatment on hospitalization gave excellent results. A somewhat higher antibiotic dosage than that applied in the usual bacterial infections is recommended in psittacosis, and to prevent recurrence the treatment should be continued for several days after the fever has subsided. The diagnostic importance of the complement fixation test is emphasized.

Paroxysmal Nocturnal Hemoglobinuria. G. W. Dean. Wisconsin M. J. 54:335-339 (July) 1955 [Madison, Wis.].

The patient whose history is presented was a 60-year-old woman who was first hospitalized in 1952 because of recurrent bronchial asthma, which had bothered her at intervals since 1944. This responded to treatment but, in the course of her examination, she gave a history of anemia since the birth of her child in 1927 and of episodes of dark urine since 1940. In recent years these episodes had been accompanied by jaundice. On the basis of numerous laboratory studies a clinical diagnosis was made of paroxysmal nocturnal hemoglobinuria, which is a hemolytic anemia also known as the Marchiafava-Micheli syndrome. Its cause is unknown, but its basic defect is in the erythrocytes, which are hemolyzed by the patient's own serum as well as by the serum of a normal person. After leaving the hospital the patient continued to have severe attacks of paroxysmal nocturnal hemoglobinuria about every two months; these alternated with milder attacks. She could almost predict the appearance of the dark urine and would become apprehensive and discouraged. The hemoglobinuria always appeared after a period of sleep, day or night, and was usually preceded by indigestion. Some attacks were precipitated by an acute upper respiratory infection. On many of these occasions she was given transfusions of whole blood and of washed erythrocytes. There was no evidence of increased hemolysis after the transfusions. During one bout of paroxysmal nocturnal hemoglobinuria, the patient's blood was thoroughly studied. The results indicated that when the patient's red blood cells were treated with trypsin, they were susceptible to hemolysis by at least one factor present in normal serum as well as acidified serum, thus proving the diagnosis of paroxysmal nocturnal hemoglobinuria. In January, 1955, during another attack of upper respiratory infection, her condition deteriorated rapidly and she became deeply jaundiced and pallid. In spite of intensive treatment, she died. Autopsy revealed a mucopurulent tracheobronchitis, obstructive pulmonary emphysema, bronchiectasis, atelectasis of the middle lobe, cor pulmonale, chronic rheumatic valvulitis, cardiac cirrhosis of the liver, hemoglobinuric tubular nephropathy, and uterine leiomyofibromas. Once the hemolytic nature of an anemia has been recognized, steps must be taken to determine whether it is of the intrinsic type, in which there is an intracorpuscular defect, or whether it is of extrinsic type, in which hemolysis is caused by extracorpuscular agents such as chemicals, drugs, animal or vegetable poisons, infectious agents, isoagglutinins, or hemolytic immune bodies. The treatment of paroxysmal nocturnal hemoglobinuria is unsatisfactory; no cures have been reported.

Clinical Features of Porphyria. R. Pimenta de Mello. Hospital 47:583-588 (May) 1955 (In Portuguese) [Rio de Janeiro, Brazil].

According to a purely clinical classification, porphyria may be classed as either congenital or intermittent acute. The disease is hereditary. Congenital porphyria renders the patient extremely sensitive to light. The disease starts with the appearance of blisters after exposure of the patient to light, followed sometimes by development of intractable urticaria. As the disease progresses, mutilation of the hands and parts of the face may occur. The urine of the patients is as red as wine. The intermittent acute form includes the (1) latent, (2) nervous, (3) abdominal, and (4) typical types of the disease. The latent type runs without clinical symptoms, but the patients eliminate uroporphyrin and coproporphyrin. The nervous type runs with paralysis and without abdominal symptoms, whereas the abdominal type is characterized by abdominal disorders without paralysis. The typical type presents both paralysis and abdominal disorders. The clinical diagnosis of intermittent acute porphyria is difficult, as the disease frequently simulates poliomyelitis, Landry's paralysis, progressive muscular atrophy, psychoses, and endocrinopathies. Employing an anatomicoclinical classification, one can class the disease as developing in the erythropoietic organs or in the liver. Erythropoietic porphyria is congenital and of the photosensitive type. Frequently it is associated with hemolytic anemia and splenomegaly. Anemia may improve after splenectomy. The hepatic form includes the nervous and abdominal intermittent acute type and the mixed type with late appearance of photosensitivity and either or both nervous and abdominal disorders. Independently of definite forms of porphyria, there are several intoxications, diseases, or conditions that cause secondary coproporphyrinuria, increased elimination of protoporphyrin and deuteroporphyrin, or presence of certain porphyrins in blood, tissue, or feces. The most frequent causal factors of either elimination or retention of porphyrins are intoxication with heavy metals; infections; rheumatic fever; pemphigus foliaceus; severe injury to the liver by certain diseases or by the use of barbituric derivatives or sulfonamide drugs; and intestinal hemorrhage. Chloroma tumors and necrotic tissues are almost entirely made up of protoporphyrin.

SURGERY

Re-Operation for Mitral Valve Disease. I. D. Baronofsky, C. Borden, R. E. Smith and J. L. Sprafka. Ann. Surg. 142:32-36 (July) 1955 [Philadelphia].

Of five patients with mitral valvular disease in whom second mitral valvuloplastic procedures were undertaken, three were women 43 years of age and two were men aged 29 and 45 years respectively. They represented three types of patients with mitral valvular disease in whom reoperation was done. The first type was represented by a patient in whom previous exploratory cardiotomy had been undertaken in order to perform a mitral valvulotomy, which, however, was omitted because of the presence of significant regurgitation with little stenosis. In this patient, the electrocardiogram showed the presence of a 90 degree electrical axis toward the right as two years passed, suggesting stenosis of the mitral valve. This was verified at reoperation. A second patient with this type of disease is reported on. It is possible that patients with severe regurgitation for whom nothing was done at the initial operation may require surgical treatment at a later date for definite stenosis. With this in mind the authors continually observe patients in whom the diagnosis of mitral regurgitation has been made for evidence of changes in the electrocardiograms, roentgenograms, or murmurs, which suggest changing lesions. If such evidence is present, exploratory cardiotomy is carried out. The second type was represented by a patient with mitral valvular disease in whom the presence of a large thrombus in the left auricle had prevented the fracture of the valve at the first operation. At the second operation on this patient, the surgeon's finger was inserted alongside the thrombus, which was well fixed to the atrial wall; an uneventful mitral valvulotomy was performed through the thrombus. Of the two remaining patients, one underwent fracture of the mitral valve after a finger dilatation had been carried out at the first operation. The fifth patient was one in whom an early attempt at the relief of mitral stenosis by one of the pioneers in the field had been made by removing a 1 cm. piece of valve. The patient improved after the operation, with a gradual reappearance of symptoms later. An excellent fracture of the anterior-lateral commissure was obtained at the second operation, increasing the size of the orifice to at least 3 to 4 cm. The last two patients presented cases of the third type, i. e., of the possible recurrence of mitral stenosis. It is suggested that reoperation in patients with an initial exploratory cardiotomy is perfectly feasible and should be attempted when warranted by the condition of the patient or by the subsequent laboratory or clinical findings.

Arterialization of the Coronary Sinus for the Revascularization of the Heart in Coronary Artery Disease: Mortality Study Following Circumflex Coronary Artery Ligation. A. A. Bakst, J. Costas-Durieux and C. P. Bailey. J. Thoracic Surg. 30:57-65 (July) 1955 [St. Louis].

The technique of arterialization that Bakst and associates used on dogs was conceived and developed by others. It consists of a two-stage operation. At the first stage, through a left-sided thoracic incision, a free segment of external jugular vein is used to anastomose the aorta to the coronary sinus. Three to six weeks later, through a right-sided approach, the coronary sinus is partially ligated over a probe to 2 to 3 mm. Subsequently, the animals are used for physiological experiments. In an effort to study the pathological effects on the myocardial venous bed of elevating the pressure within the coronary sinus by arterialization, all the animals were killed after the physiological data were obtained. For the purposes of this comparative mortality report, those animals living for four hours after the ligation of the circumflex coronary artery were classified as survivals. The circumflex coronary artery was ligated in normal dogs, with a 90% six hour mortality rate and an eventual 100% mortality rate. Ligation of the circumflex coronary artery in dogs that have had previous miscellaneous cardiac surgery resulted in a 66% mortality rate. The 33% survival rate was not apparently related to either coronary sinus pressure or the amount of retrograde blood flow from the distal cut end of the ligated coronary artery. Ligation of the left anterior descending artery in similar dogs resulted in a 60% mortality rate. Two survivors demonstrated an accessory left anterior descending artery arising from the circumflex coronary artery. This accessory vessel probably accounted for an increase in the intercoronary arterial anastomotic flow that was adequate to protect the heart against ventricular fibrillation. Ligation of the circumflex branch of the left coronary artery in animals in which the coronary sinus was arterialized for one to two months resulted in a 20% mortality. It is of interest that in two dogs that died the heart beat well for one and two hours, respectively, after circumflex artery ligation. Ventricular fibrillation ensued in both animals within five minutes of occlusion of the graft. The authors were originally impressed by the protection afforded by the anastomosis of the aorta to the coronary sinus. Ligation of the circumflex branch of the left coronary artery in animals in which the coronary sinus had been arterialized for six months produced a 66% mortality. In this group, it was impossible to demonstrate any significant protection against ventricular fibrillation afforded by arterialization of the coronary sinus. This loss of protection was accompanied by a loss of retroperfusion of the myocardium, which was explained by a marked intimal proliferation and thrombosis within the major venous tributaries of the coronary sinus.

Late Results of Cardioangiological Interventions. L. Grossi. Minerva cardioangiol. 3:203-206 (May) 1955 (In Italian) [Turin, Italy].

Grossi reports the late results on 70 patients with mitral stenosis and 10 with congenital heart disease, of whom all but two were referred by him to Prof. A. M. Dogliotti for operative intervention. The patients, who have been followed for from three months to two and one-half years, were selected on the basis of the absence of signs of an active rheumatic process and marked associated valvular lesions that contraindicated the operation, their general condition, the clinical and functional findings, and common sense. Commissurotomy was performed by means of Dogliotti's valvulotomy ring, and there were no operative deaths. One patient in whom the operation was performed on a bloodless heart after extracorporeal circulation had been established was in excellent health at the time of writing. The same is true of all the patients with the congenital condition (one each with pure stenosis of the pulmonary artery, stenosis of the aortic isthmus, valvular stenosis of the aorta, and aortopulmonary fistula; three with persistent ductus arteriosus; and three with tetralogy of Fallot). The sooner the operation is performed in patients with congenital heart disease the better the results; the most favorable time is when the patient is 6 to 10 years of age. Patients with mitral stenosis should be operated on when they are 20 to 30 years of age. Atrial fibrillation is not by itself a contraindication to the intervention. Nine women and four men of this series were suffering from total arrhythmia, and in three women and three men this was associated with signs of beginning decompensation. The intervention was successful and the postoperative course normal in all. At the time of writing the condition of the patients was excellent in 36, good in 31, and stationary in 12. The last named group consisted of patients who wanted the operation despite the author's advice. There was one death. It occurred in a patient who was greatly benefited by the commissurotomy but who died two years after the operation as the result of a sudden onset of acute pulmonary edema. A gain in weight of from 5 to 6 kg. was seen in most of the patients six months to one year after the operation. A flare-up of the rheumatic process was not observed in any of the patients; arthralgia of short duration was seen in only a few.

Metastatic Malignant Lesions of the Lungs Treated by Pulmonary Resection: A Report of 43 Cases. R. T. Hood Jr., R. P. McBurney and O. T. Clagett. J. Thoracic Surg. 30:81-89 (July) 1955 [St. Louis].

This study comprises a review of 43 cases in which pulmonary resection was performed at the Mayo Clinic as a definitive procedure for a metastatic tumor of the lung. Twenty-three of the patients were male and 20 female. The relative similarity of incidence in the sexes is in contrast to the preponderance of males among the patients undergoing pulmonary resection for bronchogenic carcinoma. The study includes all the cases in which removal of metastatic pulmonary lesions was performed prior to 1952. The procedure has been increasingly utilized during recent years. Twenty-four patients did not complain of any significant pulmonary symptoms prior to removal of their metastatic tumors. The commonest complaint among the remainder was a cough. All patients presented roentgenologic evidence of a nonobstructive pulmonary mass lesion. The size of the lesions varied from 1 to 7 cm. in diameter. With two exceptions the lesions were solitary. The metastatic tumors arose from a wide variety of primary growths. In two instances the pulmonary metastasis was removed before the primary growth was excised. The interval between the two procedures in the remaining patients varied from 2 to 270 months. The value of pulmonary resection for metastatic tumors is difficult to assess solely on the basis of survival statistics. The degree of palliation afforded likewise was not measurable. Regardless of one's opinion of the value of resection of metastatic tumors, there exists the disquieting possibility that, in a patient previously treated for malignant disease, the pulmonary lesion may be unrelated to the earlier disease. The figures of 33% and 27%, respectively, for three and five year survival periods in this study, in themselves espectable values, are of limited significance because of the mall number involved. In general, the chances of cure are lightly greater for patients with small lesions that have been iscovered more than three years following removal of the rimary growth than for patients in whom the metastasis occurred earlier. The extent of the pulmonary resection did not n itself appear to be a factor in the length of survival. Conervative resections may have more applicability for metastatic umors than for bronchogenic carcinoma, since the former are ss likely to spread by lymphatic channels. The results of this tudy seem to justify the continuance of pulmonary resection for etastatic malignant lesions of the lungs. The palliation offered noteworthy, and the prolongation of life is frequently ratifying.

urgical Treatment of Localized Emphysematous Disease. V. Weisel. Ann. Surg. **142:**17-27 (July) 1955 [Philadelphia].

Of 40 patients with severe localized, cystic, pulmonary mphysematous disease, 17 refused surgical therapy at the time f their initial evaluation, while 23 underwent surgical treatment. Follow-up inquiries of the 17 patients revealed that 9 had ied of their disease, 6 had shown progression of lesion and isability, and 2 were unchanged. This is ample evidence of the igh morbidity and mortality of this disease when untreated. n contrast 22 of the 23 patients operated on during the same eriod are alive and have been markedly improved. Of the 23 atients, 19 were adults and 4 were newborn infants. There as one death in the surgically treated group that occurred in 64-year-old man on the 14th postoperative day; death resulted om a large pulmonary embolus, which apparently originated the right saphenous vein. The principal indications for surical treatment were the complications of the lesions, namely: upture with pneumothorax and hemorrhage and overdistention ith marked compression of normal lung tissue resulting in espiratory embarrassment. The surgical technique consisted of xcision or external decompression, but whether the one or the ther was used was not an important factor in the end-results. ecause of lessened morbidity, the author prefers small excisions f the lesion or pathologically involved area of the lung. External decompressive surgery was employed only in patients for hom thoracotomy and excision were considered to carry too igh a risk. The change in respiratory physiology after surgical eatment was remarkable, and the maximum breathing capacity sually showed the greatest recovery. Most of the patients howed a return to normal of the deranged ventilatory functions fter surgical therapy; in addition, follow-up studies for more han 24 months after the operation revealed no evidence of ecurrence or progression of emphysema in the author's patients.

lood Values in Gastric Carcinoma: Preoperative and Postperative Blood Volume, Total Circulating Hemoglobin, and erum Protein in Patients with Gastric Carcinoma. B. Fretheim. . M. A. Arch. Surg. **71:**14-23 (July) 1955 [Chicago].

Fretheim examined the hemoglobin percentage, the total emoglobin, the blood volume, the red blood cell volume, and he plasma volume and also examined the serum protein concentration and the total circulating serum protein preoperatively nd postoperatively in patients with gastric carcinoma. These atients generally have a considerable reduction of hemoglobin ercentage, total hemoglobin, and red blood cell volume, as well s a moderate reduction of blood volume. The serum protein concentration is distinctly reduced, but, owing to slight or no reduction of plasma volume, the total circulating serum protein is only slightly reduced. To bring the patients up to normal values preoperatively, considerably more blood has to be supplied than can be calculated from the values found, because a large portion of the red blood cells given are hemolyzed and relatively still greater amounts of serum protein and fluid leave the blood stream again. Postoperatively, the values are again thrown out of balance. The loss of blood during gastrectomy and the following 24 hours is considerably greater than that measured by the weighing of compress blood, usually several times greater. The hemoglobin percentage and the serum protein concentration are poor guides to the amount of blood lost, as they reach the lowest value two days or several days after the loss of blood. The best guide is provided by measurement of the total hemoglobin and the red blood cell volume. The serum protein and the plasma volume are more mobile: they pass more easily back and forth between blood vessels and tissues, giving a less reliable picture of the loss of blood.

Two Hundred Cases of Exeresis for Pulmonary Tuberculosis. E. Cornet, M. Dupont and Fertil. Semaine hôp. Paris **31:**2360-2364 (July 2) 1955 (In French) [Paris, France].

An analysis is made of 200 consecutive patients with pulmonary tuberculosis treated by surgical excision. The ratio of men to women in the series was 110:90. The authors' experience with patients with more advanced disease who have to be treated by collapse therapy has been that the percentage of men is much greater. This is explained by the fact that women consult physicians earlier in the course of their disease and follow instructions more faithfully than do men. Twenty-six per cent of the 200 patients required pneumonectomy, which fact shows the severity of hospital cases as opposed to sanatorium cases. Of 21 patients with severe parenchymal involvement necessitating pneumonectomy, 16 had disease of pleural origin. In this series there was predominance of lesions of the superior right lobe and a large number of cases of retracting lobitis. Of the exereses, 22.5% were carried out after unsatisfactory collapse therapy. The mortality in the series was 14, or 17% of the patients with pneumonectomy, 5% of those with lobectomy, and 0% of those with segmentectomy. On the whole, the long-term resolution of postoperative complications was satisfactory.

Gastric Carcinoma Treated with Abdominothoracic Total Gastrectomy. B. Fretheim. A. M. A. Arch. Surg. **71:**24-32 (July) 1955 [Chicago].

The author reviews observations on 178 patients with gastric carcinoma who were subjected to total gastrectomy by the abdominothoracic approach. The series included 46 women and 132 men. There were 31 operative deaths (17.4%); in 11 of these patients death was due to infection in the operative field. Other surgical fatalities were caused by pneumonia, lung emboli, shock, cardiovascular complications, incarceration of the jejunal loop, intraperitoneal hemorrhage, and acute pancreatic necrosis. Extensive metastases caused death in three patients three or four weeks after operation. Nonfatal postoperative complications included thromboemboli, sutural insufficiency, and subphrenic abscess. More than half of the patients subjected to total gastrectomy died within one year after the gastrectomy; one-sixth survived three years; and only one in nine patients survived more than five years. The patients who died within one year after total gastrectomy generally had severe complaints in the form of anorexia, nausea, and vomiting. Their weight did not increase, they were unfit to work and generally had considerable pain. Therefore, in these patients the operation was not really indicated. The majority of patients who survived more than one year were so comfortable that the intervention must be regarded as having been justified. Total gastrectomy for gastric carcinoma is recommended in all cases in which the neoplasm has spread to such an extent that it is not possible to resect the stomach 5 cm. to both sides from the site of the carcinoma and in which radical surgery is possible. In carcinoma of the type of muciparous scirrhus, the macroscopical delimitation is difficult and the indication for total gastrectomy consequently greater. Total gastrectomy should not be resorted to as a palliative measure. A combined abdominothoracic incision permits better access and, thereby, a greater possibility of radical block dissection than an abdominal or thoracic incision. The operative mortality and the postoperative complications are so much higher in total gastrectomy than in subtotal resection, and the postoperative complaints, digestive disturbances, and reduced general condition and capacity for work are so much greater that subtotal gastrectomy is preferable when it can be carried out according to radical principles.

by a patient with mitral valvular disease in whom the presence of a large thrombus in the left auricle had prevented the fracture of the valve at the first operation. At the second operation on this patient, the surgeon's finger was inserted alongside the thrombus, which was well fixed to the atrial wall; an uneventful mitral valvulotomy was performed through the thrombus. Of the two remaining patients, one underwent fracture of the mitral valve after a finger dilatation had been carried out at the first operation. The fifth patient was one in whom an early attempt at the relief of mitral stenosis by one of the pioneers in the field had been made by removing a 1 cm. piece of valve. The patient improved after the operation, with a gradual reappearance of symptoms later. An excellent fracture of the anterior-lateral commissure was obtained at the second operation, increasing the size of the orifice to at least 3 to 4 cm. The last two patients presented cases of the third type, i. e., of the possible recurrence of mitral stenosis. It is suggested that reoperation in patients with an initial exploratory cardiotomy is perfectly feasible and should be attempted when warranted by the condition of the patient or by the subsequent laboratory or clinical findings.

Arterialization of the Coronary Sinus for the Revascularization of the Heart in Coronary Artery Disease: Mortality Study Following Circumflex Coronary Artery Ligation. A. A. Bakst, J. Costas-Durieux and C. P. Bailey. J. Thoracic Surg. 30:57-65 (July) 1955 [St. Louis].

The technique of arterialization that Bakst and associates used on dogs was conceived and developed by others. It consists of a two-stage operation. At the first stage, through a left-sided thoracic incision, a free segment of external jugular vein is used to anastomose the aorta to the coronary sinus. Three to six weeks later, through a right-sided approach, the coronary sinus is partially ligated over a probe to 2 to 3 mm. Subsequently, the animals are used for physiological experiments. In an effort to study the pathological effects on the myocardial venous bed of elevating the pressure within the coronary sinus by arterialization, all the animals were killed after the physiological data were obtained. For the purposes of this comparative mortality report, those animals living for four hours after the ligation of the circumflex coronary artery were classified as survivals. The circumflex coronary artery was ligated in normal dogs, with a 90% six hour mortality rate and an eventual 100% mortality rate. Ligation of the circumflex coronary artery in dogs that have had previous miscellaneous cardiac surgery resulted in a 66% mortality rate. The 33% survival rate was not apparently related to either coronary sinus pressure or the amount of retrograde blood flow from the distal cut end of the ligated coronary artery. Ligation of the left anterior descending artery in similar dogs resulted in a 60% mortality rate. Two survivors demonstrated an accessory left anterior descending artery arising from the circumflex coronary artery. This accessory vessel probably accounted for an increase in the intercoronary arterial anastomotic flow that was adequate to protect the heart against ventricular fibrillation. Ligation of the circumflex branch of the left coronary artery in animals in which the coronary sinus was arterialized for one to two months resulted in a 20% mortality. It is of interest that in two dogs that died the heart beat well for one and two hours, respectively, after circumflex artery ligation. Ventricular fibrillation ensued in both animals within five minutes of occlusion of the graft. The authors were originally impressed by the protection afforded by the anastomosis of the aorta to the coronary sinus. Ligation of the circumflex branch of the left coronary artery in animals in which the coronary sinus had been arterialized for six months produced a 66% mortality. In this group, *it was impossible to demonstrate any* significant protection against ventricular fibrillation afforded by arterialization of the coronary sinus. This loss of protection was accompanied by a loss of retroperfusion of the myocardium, which was explained by a marked intimal proliferation and thrombosis within the major venous tributaries of the coronary

Late Results of Cardioangiological Interventions. L. Grossi. Minerva cardioangiol. 3:203-206 (May) 1955 (In Italian) [Turin, Italy].

Grossi reports the late results on 70 patients with mitral stenosis and 10 with congenital heart disease, of whom all but two were referred by him to Prof. A. M. Dogliotti for operative intervention. The patients, who have been followed for from three months to two and one-half years, were selected on the basis of the absence of signs of an active rheumatic process and marked associated valvular lesions that contraindicated the operation, their general condition, the clinical and functional findings, and common sense. Commissurotomy was performed by means of Dogliotti's valvulotomy ring, and there were no operative deaths. One patient in whom the operation was performed on a bloodless heart after extracorporeal circulation had been established was in excellent health at the time of writing. The same is true of all the patients with the congenital condition (one each with pure stenosis of the pulmonary artery, stenosis of the aortic isthmus, valvular stenosis of the aorta, and aortopulmonary fistula; three with persistent ductus arteriosus; and three with tetralogy of Fallot). The sooner the operation is performed in patients with congenital heart disease the better the results; the most favorable time is when the patient is 6 to 10 years of age. Patients with mitral stenosis should be operated on when they are 20 to 30 years of age. Atrial fibrillation is not by itself a contraindication to the intervention. Nine women and four men of this series were suffering from total arrhythmia, and in three women and three men this was associated with signs of beginning decompensation. The intervention was successful and the postoperative course normal in all. At the time of writing the condition of the patients was excellent in 36, good in 31, and stationary in 12. The last named group consisted of patients who wanted the operation despite the author's advice. There was one death. It occurred in a patient who was greatly benefited by the commissurotomy but who died two years after the operation as the result of a sudden onset of acute pulmonary edema. A gain in weight of from 5 to 6 kg. was seen in most of the patients six months to one year after the operation. A flare-up of the rheumatic process was not observed in any of the patients; arthralgia of short duration was seen in only a few.

Metastatic Malignant Lesions of the Lungs Treated by Pulmonary Resection: A Report of 43 Cases. R. T. Hood Jr., R. P. McBurney and O. T. Clagett. J. Thoracic Surg. 30:81-89 (July) 1955 [St. Louis].

This study comprises a review of 43 cases in which pulmonary resection was performed at the Mayo Clinic as a definitive procedure for a metastatic tumor of the lung. Twenty-three of the patients were male and 20 female. The relative similarity of incidence in the sexes is in contrast to the preponderance of males among the patients undergoing pulmonary resection for bronchogenic carcinoma. The study includes all the cases in which removal of metastatic pulmonary lesions was performed prior to 1952. The procedure has been increasingly utilized during recent years. Twenty-four patients did not complain of any significant pulmonary symptoms prior to removal of their metastatic tumors. The commonest complaint among the remainder was a cough. All patients presented roentgenologic evidence of a nonobstructive pulmonary mass lesion. The size of the lesions varied from 1 to 7 cm. in diameter. With two exceptions the lesions were solitary. The metastatic tumors arose from a wide variety of primary growths. In two instances the pulmonary metastasis was removed before the primary growth was excised. The interval between the two procedures in the remaining patients varied from 2 to 270 months. The value of pulmonary resection for metastatic tumors is difficult to assess solely on the basis of survival statistics. The degree of palliation afforded likewise was not measurable. Regardless of one's opinion of the value of resection of metastatic tumors, there exists the disquieting possibility that, in a patient previously treated for malignant disease, the pulmonary lesion may be unrelated to the earlier disease. The figures of 33% and 27%, respectively, for three and five year survival periods in this study, in themselves respectable values, are of limited significance because of the small number involved. In general, the chances of cure are slightly greater for patients with small lesions that have been discovered more than three years following removal of the primary growth than for patients in whom the metastasis occurred earlier. The extent of the pulmonary resection did not in itself appear to be a factor in the length of survival. Conservative resections may have more applicability for metastatic umors than for bronchogenic carcinoma, since the former are ess likely to spread by lymphatic channels. The results of this tudy seem to justify the continuance of pulmonary resection for metastatic malignant lesions of the lungs. The palliation offered s noteworthy, and the prolongation of life is frequently ratifying.

Surgical Treatment of Localized Emphysematous Disease. W. Weisel. Ann. Surg. **142**:17-27 (July) 1955 [Philadelphia].

Of 40 patients with severe localized, cystic, pulmonary mphysematous disease, 17 refused surgical therapy at the time f their initial evaluation, while 23 underwent surgical treatment. Follow-up inquiries of the 17 patients revealed that 9 had ied of their disease, 6 had shown progression of lesion and isability, and 2 were unchanged. This is ample evidence of the high morbidity and mortality of this disease when untreated. n contrast 22 of the 23 patients operated on during the same eriod are alive and have been markedly improved. Of the 23 atients, 19 were adults and 4 were newborn infants. There was one death in the surgically treated group that occurred in 64-year-old man on the 14th postoperative day; death resulted rom a large pulmonary embolus, which apparently originated in the right saphenous vein. The principal indications for surgical treatment were the complications of the lesions, namely: upture with pneumothorax and hemorrhage and overdistention with marked compression of normal lung tissue resulting in espiratory embarrassment. The surgical technique consisted of xcision or external decompression, but whether the one or the other was used was not an important factor in the end-results. Because of lessened morbidity, the author prefers small excisions of the lesion or pathologically involved area of the lung. External decompressive surgery was employed only in patients for whom thoracotomy and excision were considered to carry too high a risk. The change in respiratory physiology after surgical reatment was remarkable, and the maximum breathing capacity usually showed the greatest recovery. Most of the patients showed a return to normal of the deranged ventilatory functions after surgical therapy; in addition, follow-up studies for more than 24 months after the operation revealed no evidence of recurrence or progression of emphysema in the author's patients.

Blood Values in Gastric Carcinoma: Preoperative and Postoperative Blood Volume, Total Circulating Hemoglobin, and Serum Protein in Patients with Gastric Carcinoma. B. Fretheim. A. M. A. Arch. Surg. **71**:14-23 (July) 1955 [Chicago].

Fretheim examined the hemoglobin percentage, the total hemoglobin, the blood volume, the red blood cell volume, and the plasma volume and also examined the serum protein concentration and the total circulating serum protein preoperatively and postoperatively in patients with gastric carcinoma. These patients generally have a considerable reduction of hemoglobin percentage, total hemoglobin, and red blood cell volume, as well as a moderate reduction of blood volume. The serum protein concentration is distinctly reduced, but, owing to slight or no reduction of plasma volume, the total circulating serum protein is only slightly reduced. To bring the patients up to normal values preoperatively, considerably more blood has to be supplied than can be calculated from the values found, because a large portion of the red blood cells given are hemolyzed and relatively still greater amounts of serum protein and fluid leave the blood stream again. Postoperatively, the values are again thrown out of balance. The loss of blood during gastrectomy and the following 24 hours is considerably greater than that measured by the weighing of compress blood, usually several times greater. The hemoglobin percentage and the serum protein concentration are poor guides to the amount of blood lost, as they reach the lowest value two days or several days after the loss of blood. The best guide is provided by measurement of the total hemoglobin and the red blood cell volume. The serum protein and the plasma volume are more mobile: they pass more easily back and forth between blood vessels and tissues, giving a less reliable picture of the loss of blood.

Two Hundred Cases of Exeresis for Pulmonary Tuberculosis. E. Cornet, M. Dupont and Fertil. Semaine hôp. Paris **31**:2360-2364 (July 2) 1955 (In French) [Paris, France].

An analysis is made of 200 consecutive patients with pulmonary tuberculosis treated by surgical excision. The ratio of men to women in the series was 110:90. The authors' experience with patients with more advanced disease who have to be treated by collapse therapy has been that the percentage of men is much greater. This is explained by the fact that women consult physicians earlier in the course of their disease and follow instructions more faithfully than do men. Twenty-six per cent of the 200 patients required pneumonectomy, which fact shows the severity of hospital cases as opposed to sanatorium cases. Of 21 patients with severe parenchymal involvement necessitating pneumonectomy, 16 had disease of pleural origin. In this series there was predominance of lesions of the superior right lobe and a large number of cases of retracting lobitis. Of the exereses, 22.5% were carried out after unsatisfactory collapse therapy. The mortality in the series was 14, or 17% of the patients with pneumonectomy, 5% of those with lobectomy, and 0% of those with segmentectomy. On the whole, the long-term resolution of postoperative complications was satisfactory.

Gastric Carcinoma Treated with Abdominothoracic Total Gastrectomy. B. Fretheim. A. M. A. Arch. Surg. **71**:24-32 (July) 1955 [Chicago].

The author reviews observations on 178 patients with gastric carcinoma who were subjected to total gastrectomy by the abdominothoracic approach. The series included 46 women and 132 men. There were 31 operative deaths (17.4%); in 11 of these patients death was due to infection in the operative field. Other surgical fatalities were caused by pneumonia, lung emboli, shock, cardiovascular complications, incarceration of the jejunal loop, intraperitoneal hemorrhage, and acute pancreatic necrosis. Extensive metastases caused death in three patients three or four weeks after operation. Nonfatal postoperative complications included thromboemboli, sutural insufficiency, and subphrenic abscess. More than half of the patients subjected to total gastrectomy died within one year after the gastrectomy; one-sixth survived three years; and only one in nine patients survived more than five years. The patients who died within one year after total gastrectomy generally had severe complaints in the form of anorexia, nausea, and vomiting. Their weight did not increase, they were unfit to work and generally had considerable pain. Therefore, in these patients the operation was not really indicated. The majority of patients who survived more than one year were so comfortable that the intervention must be regarded as having been justified. Total gastrectomy for gastric carcinoma is recommended in all cases in which the neoplasm has spread to such an extent that it is not possible to resect the stomach 5 cm. to both sides from the site of the carcinoma and in which radical surgery is possible. In carcinoma of the type of muciparous scirrhus, the macroscopical delimitation is difficult and the indication for total gastrectomy consequently greater. Total gastrectomy should not be resorted to as a palliative measure. A combined abdominothoracic incision permits better access and, thereby, a greater possibility of radical block dissection than an abdominal or thoracic incision. The operative mortality and the postoperative complications are so much higher in total gastrectomy than in subtotal resection, and the postoperative complaints, digestive disturbances, and reduced general condition and capacity for work are so much greater that subtotal gastrectomy is preferable when it can be carried out according to radical principles.

Surgical Aspects of Splenic Disease. W. H. Cole, J. D. Majarakis and L. R. Limarzi. A. M. A. Arch. Surg. 71:33-46 (July) 1955 [Chicago].

Cole and co-workers discuss observations on 137 patients in whom splenectomy was performed. Although it has been known for years that splenectomy yields very good results in familial hemolytic anemia and thrombocytopenic purpura, it has not been until the past few years that the authors have learned that good results are often obtained in acquired hemolytic anemia and secondary purpura. The indications for operation in these latter two diseases are not well defined, although the presence of some phase of hypersplenism represents the clearest indication. Accordingly, much more experience is needed in these diseases having borderline indications. In the reviewed series of 137 patients undergoing splenectomy for splenic disease, 54 had hemolytic anemia. Of this group, 40 were classified as hereditary and 14 as acquired. The important differentiating feature in these two groups is the fact that in the former there is an increased mechanical and osmotic fragility of the red blood cells, whereas in the latter the red blood cell fragility is normal. Splenectomy yielded good results in all except one of these patients with hereditary anemia. In the acquired group (in which Evans and associates have found autoantibodies, agglutinins, or hemolysins) the authors performed splenectomy on eight patients but obtained good results in only three. Splenectomy was done in 41 patients with thrombocytopenic purpura. Good results were obtained in 31 of 35 classified as idiopathic; in 6 cases classified as secondary purpura, results were good in only 3. The 35 patients who were classified as having hypersplenic states included those with primary splenic neutropenia and pancytopenia, Banti's syndrome, and Felty's syndrome. The authors obtained good results in all of the first group. For the past several years they have not performed splenectomy (one exception) in Banti's syndrome unless a portacaval or splenorenal shunt was performed at the same time. Results of the shunt operations are not included in this series. They have been able to follow all of their 22 patients having splenectomy for Banti's syndrome. There were five operative deaths in this group (22.7%); this is a higher rate than in any other group. Four of the five operative deaths were due to postoperative hemorrhage. Eight of the 17 patients surviving operation have died since leaving the hospital, 7 of hemorrhage from esophageal varices. Good results were obtained in four of eight patients with Felty's syndrome. The authors performed splenectomy for Gaucher's disease in only one patient; she is alive and well six years after splenectomy. The mortality rate in the entire series was 7.3%. It is significant that the mortality rate was lowest in the groups (hereditary hemolytic anemia and idiopathic thrombocytopenic purpura) having the best symptomatic results after splenectomy.

Total Right Hepatic Lobectomy for Cancer of the Gallbladder: Report of Three Cases. G. T. Pack, T. R. Miller and R. D. Brasfield. Ann. Surg. **142**:6-16 (July) 1955 [Philadelphia].

Since the prospect for cure of all patients with gallbladder cancer is seldom greater than 2 to 3% and since there has been only one five-year cure of gallbladder cancer achieved by cholecystectomy in the history of the Memorial Cancer Center in New York, the authors feel justified in suggesting that a total right hepatic lobectomy should be considered as the primary initial method of treatment for this condition. The more adequate exposure afforded by a right thoracoabdominal incision has made this operation safer and easier to perform. The technique of total right hepatic lobectomy is described in detail. Two of the three patients reported on, a 64-year-old woman and a 53-year-old woman, had undergone previous surgical treatment for cancer of the gallbladder that made total right hepatic lobectomies difficult (one having undergone simple cholecystectomy and intensive postoperative irradiation). Two of the three patients, the 64-year-old woman and a 65-year-old man, had extensive metastases to periportal, hepatoduodenal, and retroduodenal lymph nodes, which made the dissections arduous and the prognosis unfavorable. The older of the two female patients survived total right hepatic lobectomy for five and a half months. She received immediate postoperative high caloric and high protein feedings, which the authors consider an essential protection and necessary aid for the small remaining liver substance in the left lobe. The remarkable ability of the liver to regenerate was shown in this patient on autopsy, since the residual left hepatic lobe that contained no metastatic cancer had undergone regenerative hyperplasia so that its ultimate weight was almost 500 gm. In the male patient the technical difficulties were great because of the huge conglomerate lymph nodes obscuring the portal fissure. Because of ileus this patient did not receive immediate postoperative high caloric and protein feedings; he died on the seventh postoperative day. The left lobe of the liver weighing 400 gm. was estimated to be 50% larger than at the termination of the operation. The 53-year-old woman received a replacement of 3,500 cc. of blood. The postoperative course was uneventful. Oral feedings were started on the fifth postoperative day, and because of anorexia, cortisone was subsequently added in doses of 100 mg. daily. Convalescence thereafter was rapid. The remaining 20% of the liver resident in the left lobe was adequate and the patient's hepatic function has remained well within normal limits. The longest survival after right total hepatic lobectomy observed by the authors is for two years; this male patient, now weighing 90.7 kg. (200 lb.) and working, had a huge granuloma involving the entire right lobe.

Capillary Hemangiomas of the Skin. J. J. Modlin. Surgery 38:169-180 (July) 1955 [St. Louis].

Between 1947 and 1954, 29 girls and 13 boys with 52 capillary hemangiomas were examined and followed at regular intervals. Twenty-nine patients were followed for three or more years. Although 44 hemangiomas were noted within one week after the child was born and despite the fact that in 48 hemangiomas a history of rapid growth was obtained, only two children were brought for examination before the age of 2 months. With the exception of one 6-year-old boy, all the children were less than two years old at the time of their initial examination, and no capillary hemangiomas were noted in adults. Two patients, each of whom had one capillary hemangioma, were lost to follow-up. Of the remaining 50 capillary hemangiomas, 39 did not receive any treatment and 11 were surgically excised. Twenty-four of the 39 had completely disappeared at 1 to 4 years of age of the patient, and 14 were showing definite and continuing regression at the time of the author's report. In none of the 42 patients was there serious hemorrhage or threat to life, and there was no case of the so-called metastasizing hemangioma or other evidence of malignant tumor of vascular origin. It is emphasized that ideal treatment of infantile capillary hemangiomas consists of destruction or surgical excision early in life before the characteristic rapid growth occurs. The fact remains, however, that many lesions will be seen after enlargement has occurred, and it appears that these may be followed closely without treatment. It is probable that judicious restraint may produce a much better end-result than that obtained by well-meant but vigorously applied destructive methods of treatment. There is need for additional reports of conservatively managed cases in order to determine the true natural history of these lesions.

Chronic Appendicitis. H. W. Gallagher and A. E. M. Stevenson. Ulster M. J. 24:52-57 (May) 1955 [Belfast, Ireland].

A review of the literature indicates that authorities are not in agreement about the entity chronic appendicitis. The authors reviewed 400 consecutive patients who had been operated on for appendicitis in an attempt to clarify their own ideas about chronic appendicitis. All patients were operated on in Banbridge Hospital during a three and a half year period, beginning in mid-December, 1946. An attempt was made to trace all surviving patients after an interval of at least one year from the time of operation. Two hundred forty-one patients were interviewed and reexamined. Seventy-five others replied to a questionnaire. The patient's general practitioner sent a report in a further 51 cases. There were three postoperative deaths, and 30 patients could not be traced. A follow-up inquiry was made about the occurrence of chronic or recurrent abdominal symptoms before and after the operation. Of the 367 patients who were followed up, 222 had persistent or recurrent abdominal symptoms before the illness for which appendectomy was performed. Patients with recurrent abdominal symptoms fell into one of four groups, which can best be described as recurrent appendicitis (46 cases), recurrent abdominal colic (45 cases), recurrent or persistent right-sided pain (94 cases), and dyspepsia (37 cases). The authors stress the following points: 1. Recurrent appendicitis is a well-recognized condition and should not be referred to as chronic appendicitis. 2. Recurrent or persistent right-sided pain is undoubtedly due, in many instances, to lesions of the appendix and not infrequently precedes acute appendicitis in which the symptoms may remain right-sided. In some cases, removal of a normal appendix cures the patient, and it is suggested that cure may, at times, be psychological rather than physical. The term chronic appendicitis should be applied to cases of right-sided pain for which no other cause is found. 3. Recurrent abdominal colic frequently precedes an attack of acute or subacute obstructive appendicitis. Only rarely can the cause of the colic be diagnosed before the onset of localizing symptoms or signs. The authors feel that the term "chronic appendicitis—recurrent colic" could be used for this type of case. 4. Dyspepsia alone may precede an attack of appendicitis and sometimes follows an attack of appendicitis treated conservatively. Appendectomy should never be advised for dyspepsia unless there is other evidence that the appendix is abnormal. These cases could be termed "chronic appendicitis—reflex dyspepsia."

NEUROLOGY & PSYCHIATRY

Behavior of Chimpanzee-Avirulent Poliomyelitis Viruses in Experimentally Infected Human Volunteers. A. B. Sabin. Am. J. M. Sc. 230:1-8 (July) 1955 [Philadelphia].

Poliomyelitis is generally more severe in adults than in very young children. Immunization procedures should avoid creating a large adult population without resistance to paralytic poliomyelitis. Natural inapparent infection in childhood is the process by which the vast majority of the world population acquires immunity to poliomyelitis. Sabin attempted to determine by quantitative methods the comparative behavior in human beings of the same culture fluids that had been studied in monkeys and chimpanzees. Strains of each of three types of poliomyelitis virus, which were segregated in monkey kidney tissue culture and shown to be avirulent for monkeys by intracerebral and extraneural routes and for chimpanzees even after inoculation into the gray matter of the spinal cord, were administered to 30 human volunteers. These men were 21 to 30 years old and possessed no demonstrable antibody for the poliomyelitis viruses they received. Twenty-six men received types 1, 2, or 3 virus in doses varying from 0.001 cc. to 1 cc. in a teaspoonful of milk by mouth. The others who were without antibody for all 3 types received the type 3 virus intramuscularly. There was no virus multiplication in the mouth or anterior portion of the tongue. With the larger doses the viruses multiplied in the throat as well as in the lower alimentary tract, while after ingestion of the smaller doses no virus was found in the throat even when it continued to be excreted in the feces for four to six weeks. The smallest amount, 0.001 cc., containing approximately 10,000 tissue culture doses of virus, initiated an immunogenic alimentary infection in all human volunteers. This indicated that the human alimentary tract is more readily infected than that of chimpanzees, and chimpanzees are more readily infected by mouth than monkeys, while the reverse obtains for the nervous system, monkeys being much more susceptible than chimpanzees. No viremia was found in any of the volunteers, and there was no evidence of illness. Amounts of type 3 virus that readily produced infection after ingestion failed to do so after intramuscular injection except in one man, in whom the virus localized in the lower alimentary tract. The antibody response, which occurred in varying degree in different men, was of a higher order in those with extensive viral multiplication in the throat. No harmful mutants were found after multiplication in the alimentary tract. Similar studies are now in progress with naturally occurring, intracerebrally-avirulent types 1, 2, and 3 poliomyelitis viruses that were recovered from healthy children who had no contact with clinical cases of poliomyelitis. Studies on immunization of larger numbers of human beings are being postponed until comparative studies have indicated the best attenuated strains to use for this purpose.

Poliomyelitis and Tonsillectomy: A Report of the Medical Research Council Committee on Inoculation Procedures and Neurological Lesions. Lancet 2:5-10 (July 2) 1955 [London, England].

The first part of this report is concerned with recent tonsillectomy in its relationship to poliomyelitis. Between March, 1951, and December, 1953, reports were received by the Medical Research Council in Britain of 103 children up to 18 years of age in whom poliomyelitis developed within 91 days after tonsillectomy. Sixty-one (59%) had symptoms from 1 to 21 days after tonsillectomy. The concentration was most evident in the bulbar and bulbospinal groups where 44 (79%) occurred from 1 to 21 days after operation, compared with 38% of the spinal cases and 31% of the nonparalytic cases. Most cases occurred in the principal epidemic period, but the same pattern was seen in epidemic and nonepidemic seasons. Tonsillectomy as practiced at present added relatively few to the total number of cases of poliomyelitis reported during the study, but tonsillectomy should continue to be restricted in any area where the disease is unusually prevalent. The inquiry into the relationship between poliomyelitis and more remote tonsillectomy revealed that between mid-1951 and November, 1953, records were obtained in selected areas of England and Wales of the history of tonsillectomy at any time before the onset of paralytic poliomyelitis in 51 patients under 5 years of age and 203 patients 5 to 15 years of age. Histories were similarly obtained for the same number of matched controls. Only 2 of the patients and none of the controls under 5 years of age had had their tonsils removed. In the 5 to 15 year age group, 72 (35%) of the patients had undergone tonsillectomy compared with 44 (22%) of the controls. The differences between patients and controls were greatest in the group with bulbar paralysis, intermediate in the group with bulbospinal paralysis, and least in the group with spinal paralysis. In the bulbar and bulbospinal groups, most patients had had their tonsils removed at least one year and often five or more years before the onset of poliomyelitis. The results indicated that persons whose tonsils had been removed were more likely to develop the bulbar form of poliomyelitis than those who had not had the operation, even if years had elapsed between the removal of the tonsils and the onset of poliomyelitis.

Acute Anterior Poliomyelitis and Twinning: Clinical Considerations on Two Pairs of Twins. G. Dadone. Minerva nipiol. 5:44-49 (March-April) 1955 (In Italian) [Turin, Italy].

Acute anterior poliomyelitis occurred on the same day in a brother and sister who were three-year-old dizygotic twins. In both patients the same groups of muscles were involved by the paralysis in the same extremities, suggesting not only a specific constitutional tendency to become ill but also a sensitivity that seemed to be specific for a particular area. The onset of acute anterior poliomyelitis on the same day was also observed in four-year-old dizygotic twin brothers in whom the paralysis did not affect the same groups of muscles. Both pairs of twins had received prophylactic vaccinations against diphtheria and smallpox three months and one month, respectively, before the onset of poliomyelitis. Many workers have reported a relationship between inoculations of prophylactic vaccines and the onset of poliomyelitis after the latter was observed to arise in the extremity in which the injections had been given. This was not, however, the case with these two sets of twins. It is advisable not to vaccinate persons during an epidemic of poliomyelitis in order to avoid the possibility of favoring the onset of the disease. Dadone states that there is a constitutional tendency to contract poliomyelitis. In these patients there was almost a chronological identity in the onset of the disease. He suggests that, whenever poliomyelitis develops in one member of a set of twins, prophylactic measures be taken for the other member.

Behavior of Chlorine in Treated Tuberculous Meningitis: Its Prognostic Value. C. Marini and M. P. Prodi. Clin. pediat. 37:369-377 (May) 1955 (In Italian) [Bologna, Italy].

Children with tuberculous meningitis were studied to determine whether there is a relationship between the chlorine values of patients with this condition and its clinical course. The chlorine in the cerebrospinal fluid, blood, and 24-hour urine specimen was determined at the time of admission, every eight days during the severest course of the disease, and less often thereafter until the clinical findings and cerebrospinal fluid returned to normal. The results indicated that a progressive diminution of chlorine in the cerebrospinal fluid and the blood together with a heavy renal loss of it is generally present in patients in whom the outcome will be fatal. If however the patient's body retains chlorine by decreasing the urinary excretion of it and maintaining a normal blood level of it, the prognosis can be favorable, even if the initial condition was clinically severe. The study proved that the determination of the ratio between chloremia and chloruria is, in addition to that of the cerebrospinal fluid level, a valuable prognostic tool. While the latter reveals the severity of the local alterations, the former indicates the reactive capacity of the patient and his possibilities of responding favorably to treatment. The chloremia-chloruria ratio is more important and more useful than the chlorine cerebrospinal fluid value and it can give useful therapeutic indications. In fact, patients with tuberculous meningitis whose renal excretion of chlorine is marked, despite low blood levels of it, can be given orally or parenterally large doses of sodium chloride and its retention in the organism can be facilitated by administering desoxycorticosterone acetate (DCA), corticotropin (ACTH), or cortisone. This combination is suggested on the basis of the hypothesis that a state of hypercorticalism can favorably influence the degree of resistance of the patient to the tuberculous infection.

Analysis of 200 Patients with Closed Trauma of the Skull. A. Verjaal. Nederl. tijdschr. geneesk. 99:1799-1806 (June 18) 1955 (In Dutch) [Haarlem, Netherlands].

The cerebrospinal fluid of 200 unselected patients admitted to a general hospital with closed trauma of the skull was examined within 24 hours of the trauma whenever possible, and an electroencephalogram was made within a week of the accident. The cerebrospinal fluid of most of the patients who seemed to have an uncomplicated concussion of the brain contained blood, and the electroencephalogram showed considerable irregularities. The author feels that, in view of the histological condition, cerebral contusion would be a more appropriate diagnosis in these patients than concussion of the brain. Unless there were definite contraindications, all these patients were permitted to move about as much as they wanted. Patients with uncomplicated concussion of the brain were permitted free movement after a few days. The results of this active treatment seemed favorable.

Canicola Fever with Neurological Complications. J. E. Middleton. Brit. M. J. 2:25-26 (July 2) 1955 [London, England].

The patient with canicola fever whose case is described was a man, aged 42, who had been well until eight days previously when he noticed a tightness in the chest that was increased by deep breathing. Two days later a severe retro-orbital headache with photophobia developed, and these symptoms persisted. A week before he became ill he had purchased a puppy. The animal had discharging eyes and later developed frequency of micturition and weakness of the hind legs. When the patient was hospitalized on the ninth day of his illness, both conjunctivae were injected and there was a scanty morbilliform rash on his body. On the 10th day his condition was unchanged except that he had loose watery stools. He was given chlortetracycline, 1 gm. orally every six hours, together with vitamin B complex. On the 12th day his diarrhea and other symptoms had subsided, and the meningism, rash, and conjunctivitis had almost gone. His temperature was normal. The chlortetracycline was reduced to 0.5 gm. every six hours. He was discharged as well on the 23rd day. Absorption tests showed evidence of infection with Leptospira canicola. Convalescence was complicated by a cervical radiculitis. The right serratus anterior and right diaphragm were paralyzed, and there was transient paresis of the left thumb. Initial subjective sensory changes over the left forearm were also present. Recovery was complete 18 months after the onset of the illness. The neurological signs and symptoms in this case pointed to bilateral patchy involvement of either the cervical segments of the spinal cord or its roots or nerves, and the clinical picture resembled very closely the shoulder-girdle syndrome or neuralgic amyotrophy described by Parsonage and Aldren Turner in 1948. The author presumes that infection with Lept. canicola gave rise to an antigen-antibody reaction that presented as the shoulder-girdle syndrome. Agglutination tests on the animal's blood likewise indicated infection with Lept. canicola, but none of its other human contacts showed signs of canicola fever.

GYNECOLOGY & OBSTETRICS

Use of Hypotensive Agents in Treatment of Preeclamptic Toxemia of Pregnancy. R. R. de Alvarez. Obst. & Gynec. 6:55-62 (July) 1955 [New York].

Since the renal hemodynamics seen in the hypertensive states of pregnancy seem to be intimately associated with vasoconstriction, the antihypertensive agents selected for study by de Alvarez were those designed to reduce renal resistance to blood flow. Twenty-one patients in whom eclamptic toxemia developed during pregnancy were selected for study; in 15, preeclampsia developed in the absence of underlying disease; and the remaining 6 had essential hypertension upon which various degrees of preeclampsia were superimposed. All patients were hospitalized, and studies were begun on the renal hemodynamics after complete bed rest for 24 hours. Three hypotensive agents were studied, all of which were given intravenously. Fourteen patients were studied following the use of protoveratrine, a Veratrum viride preparation. Nine of these patients had preeclamptic toxemia alone, while the remaining five had preeclampsia superimposed upon benign essential hypertension. Four patients were given hydralazine (Apresoline) hydrochloride. The remaining three patients were treated with Serpasil (Rauwolfia serpentina). This last drug produced the fewest side-reactions; however, its use results in increased renal blood flow similar to the effect of hydralazine hydrochloride. The marked tachycardia or precipitous drops in pressure noted with Apresoline are not present following the administration of Rauwolfia preparations. Hypotensive drugs should supplement rather than replace good medical and obstetric therapy in pregnancy toxemia.

Adenocarcinoma of the Endometrium: An Evaluation of Factors Influencing Prognosis and an Outline of a Plan of Therapy Based on These Factors. G. A. Webb, A. J. Margolis and H. F. Traut. West. J. Surg. 63:407-419 (July) 1955 [Portland, Ore.].

Adenocarcinoma of the endometrium has long been relegated to a position of lesser importance in comparison with cervical malignancies, mostly because of the generally accepted view that the prognosis of adenocarcinoma of the endometrium is excellent in relation to the prognosis of squamous cell carcinoma of the cervix. The ratio of instances of adenocarcinoma of the endometrium to squamous cell carcinoma of the cervix has changed from 1:6 to 1:3 in the past two decades. One reason for this increase in fundal carcinoma may be the increasing longevity of the population, and it is also interesting to speculate whether perhaps the use of estrogens by growing numbers of the aging female population might be partly responsible for this increase. This paper reviews the patients with a diagnosis of adenocarcinoma of the endometrium seen in the University of California Hospital or its Outpatient Clinic during the years from 1915 through 1948. Cases not confirmed by histological examination as well as those of metastatic carcinoma of the uterus were excluded. There were 261 authenticated cases. Jan. 1, 1949, was set as the cut-off date, so that the five year period of survival could be estimated in all patients. Two patients were lost to follow-up and two others died, so that there remain 257 patients. The five year survival in this group was 51%. The percentage of five year survival in adenocarcinoma of the endometrium has remained stationary for the last 25 years, whereas during the same period the five year survival rate from cervical carcinoma has increased threefold. Factors influencing the prognosis of adenocarcinoma of the endometrium are discussed. A plan of therapy employing surgery and irradiation (x-rays and radium) is suggested. The preoperative diagnosis should be made (1) by examination under anesthesia and (2) by differential curettage. The choice of treatment should then be determined by the size of the uterus, the invasiveness and type of the tumor, the presence of metastases, and also the patient's general condition.

Thrombosis and Embolism After Extensive Gynecologic Operations. W. Soergel. Zentralbl. Gynäk. 77:561-571 (No. 15) 1955 (In German) [Leipzig, Germany].

Soergel reviewed the records of 2,000 women who had undergone extensive gynecologic operations during the period from March, 1951, to February, 1954, with regard to the problem of thromboembolism. During the last 18 months of this period the anticoagulant ethyl biscoumacetate (Tromexan) was used for prophylaxis and therapy. It has been ascertained that the hyperprothrombinemia that exists immediately after the operation subsides gradually on the first and second day after the operation, but then it rises again and reaches a new peak on about the sixth postoperative day. This second peak corresponds with the observation that postoperative embolism is most likely on the fifth or sixth day after operation. The author began Tromexan administration for prophylactic purposes on the fourth postoperative day. He usually discontinued it on the 10th or 12th day at first, but later not until the 12th or 14th day. The use of Tromexan is contraindicated in patients with disturbances in the blood coagulation, with liver disease, with renal insufficiency, with considerable hypertension, and in pregnant women. Prophylactic treatment with Tromexan was not used in all patients routinely but only in 201 selected from among 1,000 women. Later it was found that the selection for prophylactic therapy had not been sufficiently wide, in that all those who died of pulmonary embolism and all but four of those who experienced thrombosis and infarcts had not received prophylactic Tromexan therapy. With regard to the therapeutic use of Tromexan, the author found that treatment time in the phlebothromboses was reduced by about one-third; the subsidence of edema and the recanalization of the veins also was more rapid; extension to the femoral vein was often prevented; and many of the late sequelae of phlebothrombosis were prevented. Severe hemorrhages that could be ascribed to no other cause than the Tromexan were observed in eight cases. The author concludes that Tromexan is valuable in the prophylaxis as well as in the treatment of postoperative embolism. He still prefers selective to routine prophylactic treatment with Tromexan. He feels that the following groups should be protected against thromboembolism by the prophylactic administration of Tromexan: those whom Rehn regards as the thromboembolic type; those who have been operated on for myoma or carcinoma, or who have severe inflammations; those over 45 on whom plastic repair is done; those who are exhausted physically and mentally; those with cardiovascular defects; all those who are over the age of 50; those with varicosities; those who had a tubal abortion; and all patients in whom a hyperprothrombinemia of over 80% is established on the third day after operation. Atmospheric factors should also receive attention in that hyperprothrombinemia is particularly dangerous when the barometric pressure decreases rapidly. Other important prophylactic measures include prevention of infection, bandaging the legs before operation in patients with varicosities, continuous blood pressure control after operations, breathing exercises facilitating the suction effect of the diaphragm, elevating the foot of the bed, and early rising after operation. The hemorrhage that might be brought on by coumarin preparations is a lesser threat than is embolism.

Prophylaxis of Thromboembolism in Surgical Gynecology with a Coumarin Derivative and Its Antagonist Vitamin K_1. H. Röttger. Zentralbl. Gynäk. 77:571-577 (No. 15) 1955 (In German) [Leipzig, Germany].

Since an oil-soluble vitamin K_1 preparation has become available that will normalize the coagulation process within a few hours, it has been possible to use so-called super Dicumarol preparations in the prophylaxis and therapy of thromboembolism. This report is concerned with 3-(1′-phenylpropyl)-4-oxycoumarin, which has been introduced into clinical use under the term Marcumar. It differs from bishydroxycoumarin (Dicumarol) in that it contains only one oxycoumarin group. The author comments on the action mechanisms of this and other coumarin derivatives as well as of their antagonist vitamin K_1. On the basis of experiences with Marcumar in the prevention of thromboembolism after gynecologic and obstetric operations, the author stresses particularly the protracted and uniformly persistent action of this coumarin derivative, which results in a uniform reduction of the coagulation factors and in a leveling off and is therefore particularly suited to prolonged prophylaxis and therapy. The thromboplastin time does not have to be determined so frequently. If the values should go too low, as the result of excessive dosage or hyperreaction on the part of the patient, the coagulation mechanism can be quickly restored with the aid of the oral administration of the oil-soluble vitamin K_1 preparation.

Female Vaginal Cycle: Review and Normal Cytological Material. Bibl. læger 146:213-246 (Nov.-Dec.) 1954 (In Danish) [Copenhagen, Denmark].

The author's investigations, in agreement with earlier investigations, confirm that there is a well-defined, cytologically demonstrable vaginal cycle, which can, according to the varying relations between the different blood cell types, their morphology, and their grouping, together with the presence of erythrocytes and leukocytes, be divided into different phases of which the ovulation phase is the most striking. The most constant factor from cycle to cycle is the eosinophilia. If the daily variation in eosinophilia is shown in curves, characteristic curves appear with a maximal plateau about the time of ovulation and a steep fall in the postovulatory phase. Comparison between the average eosinophilia curve and the estrogen excretion curve shows clear agreement.

Problems Associated with Treatment of Cancer of the Endometrium. J. M. Sadler. Am. J. Obst. & Gynec. 70:17-28 (July) 1955 [St. Louis].

The use of preoperative irradiation in the form of intrauterine radium followed by total hysterectomy and bilateral salpingo-oophorectomy in six to eight weeks has been advocated by many as the method resulting in the best survival rate in women with cancer of the endometrium. This study was undertaken to evaluate the use of radium in this manner. It was found that the insertion of radium sources into the uterine cavity is inaccurate as to placement and distribution. There is danger of perforation of the uterus and of spread of infection or tumor cells. Five thousand milligram hours of intrauterine radium do not deliver enough gamma roentgens or "tissue" roentgens to important points in the pelvis to be cancerocidal. A method of staging of adenocarcinoma of the endometrium is presented, based on operative findings and pathological study of removed tissue. A review of 99 cases revealed residual carcinoma in 38% of stage 1 and 88% of stage 2 lesions after preoperative intrauterine irradiation with radium. Cancerous involvement of the myometrium was not influenced by irradiation of this type and the recurrence rate in stage 2 growths was 29%. The lowest recurrence rate was obtained with surgery alone. Vaginal hysterectomy was superior to radium alone in a few selected poor-risk patients. The results with x-ray and radium therapy alone were poor. The few cases presumably cured by this method may have been superficial lesions of low-grade malignancy or of the polypoid type with the curet being largely responsible for eradicating the tumor. Surgery has proved to be the best method of therapy for this disease in the author's clinic. A more extensive operation is described and is being utilized. By employing this operation, which includes pelvic lymphadenectomy, the author hopes to reduce the number of recurrences in patients whose disease extends beyond the limits of the uterus.

The Diagnosis and Prognosis of Female Genital Tuberculosis. B. P. Zummo, H. Sered and F. H. Falls. Am. J. Obst. & Gynec. **70**:34-43 (July) 1955 [St. Louis].

Studies made at Cook County Hospital in Chicago convinced Zummo and associates that tuberculosis of the female genital tract is not so rare as is generally believed. Since January, 1948, they made a study of 64 patients with genitoperitoneal tuberculosis; 52 patients were operated on, and 12 were not. Of the surgical group, 36 cases were correctly diagnosed before surgery, while 16 were misdiagnosed and initially operated on for other conditions than genital tuberculosis. Of this latter group, 11 were subsequently reoperated on, after a course of drug therapy. Genital tuberculosis, silent or active, may be one of the most difficult gynecologic diagnoses to make, because of the manner in which it masquerades as other gynecologic conditions. In this series, 25 patients gave evidence of pulmonary involvement; 10 patients showed evidences of gastrointestinal abnormalities, of which seven were suggestive of tuberculous involvement. Endometrial and cervical histological biopsies are useful, as they do not compete with bacteriological studies but are complementary. Hematological studies show two important features: (1) a relative or absolute leukopenia will be noted in most cases of genital tuberculosis, and (2) at least 50% of patients with active infections will have abnormally low hemoglobin levels. The discouragingly low incidence of positive smears by the Ziehl-Neelsen technique indicates the desirability of further exploration of the fluorescing auramine technique. A follow-up study of 28 patients treated with accepted procedures of the day (1945 to 1947, inclusive) disclosed that within two years after leaving the hospital 18 were dead, 4 were alive, and 6 were missing. Presumably one or more of the latter must have also died. The introduction of streptomycin was a milestone in the efforts to arrest or cure genital tuberculosis. The combination of the streptomycin group with *p*-aminosalicylic acid (PAS) and/or isoniazid has dramatically changed the usual chain of events. Silent lesions in the endometrium and/or oviducts respond promptly to these drugs. Pregnancies are now known to have occurred after drug therapy provided the oviduct had not been occluded or distorted or the mucosa too extensively involved. More advanced pelvic lesions still require prolonged and diligent supervision. Many patients heretofore considered candidates for surgery have been spared the ordeal and its possible associated complications because of early diagnosis and response to the drugs. However, in many instances subsequent surgical intervention is still necessary. This is particularly true of those patients who present adnexal masses, abscesses, prominent thickenings and infiltrations, and ascites.

PEDIATRICS

Congenital Heart Disease in Infants Diagnosed by Aid of Heart Catheterization and Angiography. I. Boesen, J. Lind, B. Merrild-Hansen and others. Ugesk. læger **117**:707-712 (June 2) 1955 (In Danish) [Copenhagen, Denmark].

Congenital heart disease was diagnosed clinically and by means of heart catheterization and/or angiography with intracardial injection of contrast substance in 34 out of 37 infants examined; 17 were theoretically operable. In 11 cases there was hypertension in the pulmonary artery combined with septum defect and left-right shunt. The examinations disturb the infants but little, and the results allow operation to be recommended in a number of patients on a considerably more certain diagnostic basis than previously.

Treatment of Infantile Cerebral Palsy with Glutamic Acid. N. S. Dragunova. Pediatriya pp. 59-63 (March-April) 1955 (In Russian) [Moscow, U.S.S.R.].

Glutamic acid and its amide, glutamin, have a stimulating effect on body metabolism and especially on brain tissue. Glutamic acid was used in the treatment of 50 patients. Forty-seven had various forms of cerebral palsy, of whom 10 had received no prior therapy, and 3 had microcephaly. On the whole, the results were good; they were excellent in the children who had not been previously treated. Very young children with severe disease were not much benefited. The intravenous route of administration was found to be traumatizing and was replaced by the oral route. In contrast to other workers, the author used small doses: one teaspoonful of a 1% solution of glutamic acid in a 40% solution of fructoglucose three times a day in *children of preschool* age and a *tablespoonful* for older children. These doses were administered after meals. Some children became restless and overstimulated, and their dosage had to be cut or temporarily stopped. Otherwise there were no untoward effects of therapy. Glutamic acid had an important effect on the psychic state of these children. Their apathy disappeared and they became lively and interested in their surroundings. Intellectually they became stronger. Their freedom of motion was extended. Hypersalivation was reduced. In some cases epileptic fits were obviated. Glutamic acid therapy can be used satisfactorily in combination with other treatments such as physiotherapy. Its effects become noticeable after the administration of 250 or 300 gm. of the 1% solution. For maximum effect a course of treatment must extend over a period of four or five months. The course can be repeated one or two months later.

**Tuberculous Morbidity in Infants Vaccinated with BCG in Wa
saw.** H. Zapasnik-Kobierska and M. Stopnicka. Rev. tuber
19:369-383 (No. 4) 1955 (In French) [Paris, France].

Two hundred five BCG-vaccinated children, aged from 2
15 years, were referred to a special clinic in Warsaw, Polan
for symptoms presumed to be tuberculous. Some of these p
tients had already received antituberculous therapy. The dia
nosis proved to be correct, however, only in 22 of the childr
(11%). There were 15 cases of tracheobronchial adenopath
2 of pleurisy with effusion, one of tuberculous uveitis, and
cases of calcified lymph nodes. In only one of these patie
was the vaccination considered to have been completely effe
tive; the other cases of tuberculosis cannot be taken as eviden
against BCG. The 183 children with false diagnoses of eig
different forms of tuberculosis had a wide variety of conditio
that often needed treatment of long duration. The three prin
pal sources of error were: (1) wrong interpretation of
tuberculin test; (2) wrong interpretation of chest roentge
grams; and (3) failure to ask whether the child had been v
cinated with BCG or not. It is clear that tuberculosis devel
rarely in children who have been properly vaccinated with BC
The diagnosis of tuberculous disease must not be made ligh
or quickly, for fear of improper therapy and consequent ha
to the patient as well as unfavorable publicity for the B
vaccination program.

**Active Immunization Against Diphtheria in Nurslings with A
toxins Adsorbed on Aluminum Hydroxide and Aluminum Ph
phate: Comparative Responses to the Two Vaccines.** A. Jemn
Minerva nipiol. **5**:41-44 (March-April) 1955 (In Italian) [Tur
Italy].

The immunizing efficacy and the eventual reactions follo
ing antidiphtheria vaccination with anatoxins adsorbed
aluminum hydroxide and on aluminum phosphate, respective
were studied in two groups of infants most of whom were nu
lings in the first year of life. The first vaccine was used for 38
fants, 10 of whom were born prematurely; the second was us
for 41, and of these 7 were born prematurely. The infants we
given two injections of each vaccine, the first in a 1 cc. dose,
second, four weeks later, in a 0.5 cc. dose. The inoculations we
given intramuscularly because with this route the formation
nodules at the site of injection is prevented and the immunizati
is better. There was no local reaction in any of the infants a
febrile reactions, when they occurred, were commoner in the p
mature infants; they were always, however, mild or moderate
degree. Immunity was increased in all; after 30 days, resu
of the Schick test were negative in 37 (97.4%) infants of t
first group and in 38 (92.7%) of those in the second group.
one premature infant of the first and in three normal infan

of the second group, the test gave a reaction that was slightly positive. The results of this study indicated that one vaccine is not superior to the other with regard to increasing immunity and causing febrile reactions.

UROLOGY

Carcinoma of the Female Urethra: Review of the Literature: Report of Eight Cases. G. E. Fagan and A. T. Hertig. Obst. & Gynec. 6:1-11 (July) 1955 [New York].

Fagan and Hertig discuss incidence, symptomatology, site of origin, pathological aspects, treatment, and prognosis of carcinoma of the female urethra on the basis of literature reports and of eight additional cases, which were observed at the Free Hospital for Women, Brookline, Mass., from 1935 through 1954. All were of squamous or transitional cell type. During this time there were 52,459 gynecologic admissions. The ages of the eight patients ranged between 40 and 73 years. Grossly the appearance of the squamous and transitional cell carcinomas varies, depending upon the stage of the disease. Initially the process is well localized. It may start as a small, papillomatous mass protruding above the surface or as an irregular thickening and induration of the mucosa and adjacent tissue. The initial lesion may appear as a small, spreading, superficial ulcer. As the disease progresses, the lesion may become a soft, fungating mass varying in size, which bleeds readily upon manipulation. Microscopically the squamous cell carcinomas are similar to such carcinomas of any other area. Varying degrees of dedifferentiation may be found so that the tumors may vary from a grade 1 with pearl formation to the highly anaplastic grade 4 type. All tumefactions and all suspicious lesions of the female urethra should be regarded as malignant until proved otherwise. The inguinal regions should be examined carefully for palpable nodes in the presence of lesions of the urethra. The authors mention types of treatment advocated by a number of authors and say that in the eight patients in this series only one had lymph node involvement proved by biopsy at the initial operation. She received local irradiation to the lesion and bilateral groin dissection followed by radon seed implantation to the operative site and roentgen therapy to the pelvic portals. Of the remaining seven patients, three were given only local irradiation with radium or radon seeds and a fourth received local irradiation after excision of the lesion with the diathermy loop. One patient underwent resection of the anterior vulva and left side of the urethral meatus followed by radium locally to the operative site. The treatment of choice for one patient was local irradiation with radium and radon seeds followed by roentgen therapy to the involved region. The last patient in this series received local irradiation following excision of the tumor with the diathermy loop plus roentgen therapy to the pelvic portals. Three patients died within one year. One patient is alive and well four years and seven months following initial therapy. Four patients were alive and well 10 years later. A recurrence developed in one of these four after 10 years, but she is alive and well three years after her second operation.

Recent Therapy of Phosphocalcic Urinary Lithiasis. R. Génot. Presse méd. 63:932-934 (June 18) 1955 (In French) [Paris, France].

The value of two relatively new therapeutic agents in the treatment of phosphocalcic urinary lithiasis is examined. Alumina gels in association with a diet low in phosphorus and calcium were tried in 15 patients with lithiasis with mediocre results. Urinary excretion of phosphates was in fact reduced but only in response to large doses of the drug and not enough to warrant continuation of treatment. Furthermore, calcium excretion was slightly increased. The author also examined 538 specimens from 100 patients before and after injections of hyaluronidase and found no significant changes in the number of colloidal particles, regardless of dosage used or interval after injection. The drug is incapable of preventing the appearance of (1) lime oxalate crystals in normal or lithiasic persons who have received 50 gm. of rhubarb compote; (2) uric acid crystals in a patient with that tendency who has eaten a meal rich in purine; or (3) lime phosphate crystals in a predisposed patient who has received calcium and alkalines simultaneously. The areas of therapy of urinary lithiasis in which real progress has been made recently are treatment of urinary stasis by surgical means; treatment of hyperconcentrations of precipitable material, thanks to the systematic search for hypercalciuria and hyperphosphaturia and their causes; and treatment of urinary alkalosis with drugs acting on ureolytic germs and better acidifying agents.

Indications for and Results in Retropubic Prostatectomy. O. A. Nelson. Surg., Gynec. & Obst. 101:80-84 (July) 1955 [Chicago].

Nelson defines retropubic prostatectomy as the removal of the prostate gland in part or in its entirety through a suprapubic extravesical incision. The reason for operating through the space of Retzius is to prevent the various complications that occur after the transurethral, perineal, or suprapubic-transvesical operation. Between July 1, 1951, and June 30, 1954, Nelson's group performed 238 retropubic prostatectomies for benign obstruction and 12 for early carcinoma. They also performed 291 transurethral resections, and 27 transvesical prostatectomies combined with vesical diverticulectomy. The results confirmed the basic principle set forth by Millin that an operation through the space of Retzius avoids damage to the structures that are important to vesical and urethral function. Postoperative cicatrization in the space of Retzius does not interfere with vesical or urethral drainage. Surgical shock and postoperative pain were definitely less after the retropubic procedure than after the transvesical operation. The outstanding feature of retropubic prostatectomy was the prompt recovery. After removal of the catheter, the majority of patients have very little dysuria or frequency of urination. The clearing of pus and organisms from the urine was more prompt than after any of the other types of prostatectomies. Another factor that contributes to the early, complete, and permanent return of normal vesical function after the retropubic operation may be the interruption of the enlarged sinuses in the prostatic capsule. With hyperplasia of the gland there is, practically always, enlargement of the blood sinuses in the capsule. When these sinuses are unusually enlarged, the condition is comparable to varicosity of the lower extremity. If varicosity of the leg causes suffering, the patient usually gets relief from either ligation or stripping of the veins. Therefore, it seems logical that the ligation of sinuses in the prostatic capsule incident to the retropubic procedure may be of advantage. Practically all types of prostatic obstruction, regardless of the size of the gland, can be removed retropubically. However, many of the small glands can be removed transurethrally with fewer disturbances to the patient than by an open operation. Certain concomitant conditions such as neoplasm or diverticulum of the bladder at times make the transvesical operation the preferable procedure.

Carcinoma of the Prostate: A Clinical and Steroid Metabolic Study. G. Birke, C. Franksson and L.-O. Plantin. Acta chir. scandinav. 109:129-149 (No. 2) 1955 (In English) [Stockholm, Sweden].

This report is concerned with the elimination of androgens in the urine of 64 patients with prostatic cancer after various therapeutic measures. The diagnosis of prostatic cancer was made after palpation per rectum and was corroborated by urethrocystographic or histological examination. Roentgenologic examination of the skeleton (pelvis and lumbar spine) was carried out in all patients, and skeletal metastases were found in 31 patients. The authors found that in untreated patients with prostatic carcinoma the excretion of androgens (chemically estimated as androsterone and etiocholanotone) is—if there is any difference at all—lower than in normal males. Orchiectomy reduces the production of androgen metabolites, but within one month the excretion tends to reach or exceed the preoperative values. When orchiectomy is followed by adrenalectomy, the androgen metabolites disappear completely from the urine. Stilbestrol in a dose of 30 mg. daily totally eliminates the testicular production within five days. Ten milligrams daily is the lowest dose that has the same effect within three weeks and 5 mg. daily, in long-term treatment. Cortisone in a dose of 50 to 75 mg. daily totally depresses the androgen production of the adrenals. In untreated cases the production of androgens can be totally eliminated by a combination of Stilbestrol and cortisone. There is a distinct correlation between clinical effect and excretion of androgens. Patients with a high steroid excretion which has been substantially reduced by the respective androgen-controlling measures present a good clinical effect. This is more pronounced in orchiectomy than in measures to reduce the adrenal production of androgens. Patients with a low excretion of androgens, who therefore show a poor reduction after androgen-controlling measures, present an unsatisfactory clinical response to the various therapeutic measures.

THERAPEUTICS

Fatal Anuria from Phenylbutazone. C. Toussaint, J. Brauman, J. Smulders and P. P. Lambert. Acta clin. belg. **10**:224-243 (May-June) 1955 (In French) [Brussels, Belgium].

A 52-year-old woman received two intramuscular injections of 5 cc. each of Irgapyrin on two successive days for a left sciatica. Two days after the second injection she took a tablet of novalgine-quinine after which she felt ill, vomited, and had fever. The next day there was complete anuria, lasting until a week before her death 17 days later. Death occurred from pulmonary edema with cardiac insufficiency caused by water retention, despite repeated massive peritoneal dialyses. One hundred forty-five grams of urea were extracted by this method and most of the electrolyte disturbances were corrected, but it was difficult to keep the osmotic pressure of the dialyzing fluid higher than that of the plasma. Since the patient was obese, emptying of the abdomen had to be accomplished through small incisions of the abdominal wall, into which polyethylene tubes were placed. There was a considerable amount of intraperitoneal retention. Marked hyperglycemia occurred after the last two dialyses. The development of the various renal clearances gave a bad prognosis for this nephropathy; the urea and creatinine clearances did not rise but remained almost constant. The kidney lesions seen at autopsy appeared to have been caused by prolonged ischemia. Acute arterial hyalinosis was noted in a number of organs. The lesions resembled those seen in experimentally induced renal insufficiency and are probably caused by the same mechanism.

Gastroscopic Observations of the Anticholinergic Effect of Pro-Banthine® on Gastric Motility and Pyloric Function. H. Barowsky. Am. J. Gastroenterol. **23**:557-563 (June) 1955 [New York].

This study on the effect of anticholinergic drugs on gastric motility was carried out to substantiate and amplify previous observations and to obtain more information on the degree of gastric inactivity, on the doses required, and on the differences between parenteral and oral administrations. The gastroscopic method of investigation was selected because it was felt that it was objective and would therefore be most reliable. The patients selected for this study complained of upper abdominal pain. They were all ambulatory and were observed in the outpatient department. Fifty gastroscopies were performed on 20 men and 20 women, ranging in age from 17 to 72 years. Ten had duodenal ulcer, 2 gastric ulcer, 5 gallbladder disease, 5 chronic gastritis, and 18 functional dyspepsia. Pro-Banthine, which is a brand of propantheline bromide, was administered intramuscularly to one group and orally to another. In some instances, on different occasions, the same patient was exposed to both types of tests. It was found that when Pro-Banthine is administered in adequate doses it will cause relatively complete gastric inactivity. Gastric peristalsis stops rather suddenly and leaves the stomach in a relaxed state. At the same time, the rhythmic opening and closing of the pylorus ceases and a relative paralysis ensues. This ability to cause gastric motor inactivity offers a reliable method for testing anticholinergic drugs in human subjects. In some instances, the anticholinergic drug will also cause a fading of the orange-red color of the gastric mucosa. The minimal effective dose varies with the mode of administration. Uniform cessation of peristalsis was obtained with only 10 mg. when given intramuscularly, whereas as much as 30 mg. had to be used orally to obtain the same effect. The length of time required for the drug to become effective was also dependent on the mode of administration; it took approximately 6 to 7 minutes when the medication was given intramuscularly and as much as 15 to 25 minutes when taken orally. Increased dosage did not seem to affect these time factors. Complete gastric inactivity lasted approximately one hour to one hour and 10 minutes. For an additional few minutes, diminished peristalsis was observed, then normal gastric activity ensued. Increased doses did not prolong the action of the drug. Both the intramuscular and oral routes of administration resulted in approximately the same duration of action.

Effects of Large Doses of Chloramphenicol on Human Subjects. I. H. Krakoff, D. A. Karnofsky and J. H. Burchenal. New England J. Med. **253**:7-10 (July 7) 1955 [Boston].

This study was undertaken to investigate the effects of large doses of chloramphenicol in patients with neoplastic disease, since if this drug were a consistent bone marrow depressant it might have therapeutic effects similar to those observed with other bone marrow depressants, such as nitrogen mustard, 6-mercaptopurine, and the folic acid antagonists, and might therefore be useful in certain forms of neoplastic disease. Four patients with inoperable and far advanced cancer were treated with chloramphenicol by mouth. The following diagnoses were made: carcinoma of the vagina, with local extension; perithelial sarcoma, with cerebral invasion; melanocarcinoma, with widespread metastases; carcinoma of the breast, operated on and nonrecurrent; and carcinoma of the rectum, with abdominal and cerebral metastases. The dosage was begun at conventional levels and was gradually increased until the maximum tolerated daily dose of 6, 8, or 12 gm. was achieved. Hematological studies consisted of daily hemoglobin, leukocyte, and reticulocyte determinations. Differential leukocyte counts and platelet and erythrocyte counts were performed two or three times weekly. Bone marrow examinations before, during, and after treatment were performed on three of the four patients. No effect on the course of the malignant diseases was observed. Minor hematological abnormalities and severe glossitis occurred in three patients, the glossitis preventing continuation of the drug. The tongue in these three patients was reddened, edematous, smooth, and very painful. Similar changes were seen in the buccal and pharyngeal mucosa. When the drug was stopped these signs disappeared in three to five days. Tongue and mucosal changes were produced a second time in two of the patients. Severe hematological depression and bone marrow abnormalities occurred in one patient, who tolerated larger doses without glossitis. All abnormalities were reversible on cessation of the drug. In the patients in whom some depression of the formed elements of the blood had resulted from large doses of chloramphenicol, hematological idiosyncrasy did not appear when small doses were readministered. This argues against the concept of drug idiosyncrasy as a mechanism of hematological depression in these patients. It was found also that a fall in the reticulocyte count is the earliest sign of bone marrow intoxication.

Treatment of Intractable Pain with Large Doses of Morphine and Diamino-Phenylthiazole. F. H. Shaw and A. Shulman. Brit. M. J. **1**:1367-1369 (June 4) 1955 [London, England].

The authors report on the use, in 35 cases, of the morphine antagonist 2:4-diamino-5-phenylthiazole hydrobromide, which, while having little effect on the analgesic properties of morphine, reveals marked and lasting antagonism to its respiratory depressant effect and thus renders the clinical use of large doses of morphine safe. The administration of small dosages of morphine at frequent intervals should be abandoned. One should aim at large—1 to 2 grains (65 to 130 mg.)—doses of morphine, which are sufficient to produce an analgesia of six to eight hours' duration and which nevertheless still keep the patient alert. The principle of the treatment consists in giving gradually increasing amounts—.25 grain (16 mg.) increments—of morphine accompanied by diamino-phenylthiazole (15 mg.) over a period of one or two days until the desired degree of analgesia is obtained. In cases of very severe pain it may be necessary to give doses of morphine of up to 2 grains (130 mg.) three or four times a day. Diamino-phenylthiazole is a safe drug. The dose is 15 mg. intramuscularly; as much as 100 mg. has been given without ill-effect, but careful administration is advised as these high doses are approached. Slow and irregular breathing is not a sign of respiratory danger, provided that the respirations are deep and cyanosis is not present. Diamino-phenylthiazole will increase the depth rather than the rate of respiration. For more rapid action, the diamino-phenylthiazole may be injected intravenously. Diamino-phenylthiazole given in therapeutic doses to a morphinized patient causes practically no side-effects. There are no pharmacological contraindications to the use of diamino-phenylthiazole with hyoscine, atropine, barbiturates, or chlorpromazine. The authors present tabulated data on 10 patients and brief histories of 2 of the 35 patients treated with morphine and diamino-phenylthiazole for intractable pain. Another table lists the dosages required for complete relief from pain in all 35 patients. Diamino-phenylthiazole was used also in a few cases of neonatal asphyxia, in methadone hydrochloride poisoning, and for the relief of postoperative pain. In the last-mentioned example the ability of the patient to cough painlessly was important.

Advanced Breast Cancer in Women: Complications of Hormonal Treatment. V. Faria, G. Scarinci and W. Sylvestre. Hospital 48:611-616 (May) 1955 (In Portuguese) [Rio de Janeiro, Brazil].

The use of male sex hormone in women with inoperable breast cancer or in the postoperative period of mastectomy produces satisfactory results in the majority of the cases. The general state of health of the patient improves, anemia and pain disappear, and the body weight increases. The results simulate those of a clinical cure. Frequent unpleasant but not severe complications are hirsutism, increased libido, change of voice and complexion to those of a masculine type, and acne. All of these complications disappear or greatly improve a few weeks or a few months after discontinuance of the treatment. Severe and often fatal complications of hormonal treatment include edema formation, hypercalcemia, and aggravation of the disease. Edema manifests itself by progressive increase in weight. If it is not controlled by a salt-free diet and administration of mercurial diuretics, the hormonal treatment should be discontinued. Discontinuance of hormonal treatment is indicated if edema is acute or generalized, especially if it involves the arm on the side on which mastectomy was performed. Edema in patients with heart disease is another indication for discontinuance of hormonal treatment. Hypercalcemia is occasionally observed in patients with cancer. Its presence is a contraindication to hormonal treatment. Appearance of calcemia in the course of the treatment indicates toxicity and calls for its immediate discontinuance. Early symptoms are somnolence and headache. If the treatment is not discontinued and the condition is not controlled, vomiting, abdominal pain, diarrhea, and renal insufficiency follow. Aggravation of cancer as a result of male hormonal treatment may occur in a small percentage of cases. The androgens accelerate the course of visceral and skeletal metastases and the initial cancer lesion. The general state of health of the patient rapidly deteriorates, the patients have no appetite for food, and cachexia rapidly progresses. However, the symptoms and the disease may become static by discontinuation of hormonal treatment.

Possibilities for Complete Parenteral Nutrition. A. Wretlind. Nord. med. 53:1013-1019 (June 30) 1955 (In Swedish) [Stockholm, Sweden].

Amino acids administered parenterally are utilized for synthesis of the body's protein and can be given to maintain or improve the protein nutrition. Parenteral nutrition includes amino acids and salts and carbohydrates in the form of glucose or fructose together with vitamins. By infusion of amino acids with carbohydrates, positive nitrogen or protein balance can be achieved in a number of cases even though the body's caloric need is not covered. If parenteral nutrition is to be complete, amino acids, glucose, and fat must be present in the solution. Fat in an emulsion for intravenous use must be finely dispersed; the aim is usually to keep the diameter of the particles at .2—1μ. Parenteral administration of fat, so that the entire caloric requirement can be met parenterally, is being studied intensively, and routine administration of amino acid-glucose-fat emulsions containing the necessary salts and minerals in conditions where complete parenteral nutrition is necessary may be looked for in the near future. No method is at present available for producing these emulsions in such a way that they may be stored for any length of time.

Triethylene Melamine (TEM) in the Treatment of Malignant Lymphoid Disease. C. K. Hambly and T. I. Robertson. M. J. Australia 1:900-911 (June18) 1955 [Sydney, Australia].

Triethylene melamine (TEM) is a white crystalline powder structurally related to nitrogen mustard and especially to the active ethylene-imonium transformation product formed from nitrogen mustard in tissue fluids. The authors gave triethylene melamine to 37 patients, selected for treatment with this drug because of generalized disease of hematopoietic or lymphoid tissue or because of resistance to radiotherapy. There were 12 patients with Hodgkin's disease, 10 with chronic lymphocytic leukemia, 9 with lymphosarcoma, 3 with follicular lymphoma, and 3 with reticulosarcoma. The diagnosis was confirmed in each case by biopsy of a lymph node. The drug was given also to one patient with polycythemia vera, to 2 with malignant melanoma, and to one with Lœffler's syndrome, making a total of 41 patients. The investigation extended over a period of 18 months. Postmortem examinations were made on 11 of 20 patients who died during treatment. Triethylene melamine proved to be of most value in chronic lymphocytic leukemia, in stages 2 and 3 of the malignant lymphoid diseases, and in polycythemia vera. It was, however, not the treatment of choice in these diseases. It was of limited value in advanced disease, and its efficacy was directly related to the patient's general physical condition. It has been found possible to use a lower dose than generally reported. This is attributed to giving the drug to the fasting patients with preliminary alkali, thus insuring constant absorption. The hematological effects were most pronounced on neutrophil cells, platelets, and the malignant lymphocytes. Toxic effects have been observed in the bone marrow, the liver, and the gastrointestinal, renal, and central nervous systems, together with minor skin eruptions. The drug is dangerous to patients in poor physical condition, but it is worthy of further trial in the treatment of nephrotic edema, lupus erythematosus, and Lœffler's syndrome.

The Clinical Significance of Positive Cultures and of Isoniazid-Resistant Tubercle Bacilli During the Treatment of Pulmonary Tuberculosis: Report to the Tuberculosis Chemotherapy Trials Committee of the Medical Research Council. W. Fox and I. Sutherland. Thorax 10:85-98 (June) 1955 [London, England].

A study was made on 234 patients with pulmonary tuberculosis who were treated with isoniazid alone (100 mg. twice daily) for three months. The patients were classified from the bacteriological findings at the end of two months into groups of 91 with negative cultures, 58 with strains sensitive to isoniazid, 47 with moderately resistant strains, and 38 with strongly resistant strains. These bacteriological findings were first related to the clinical characteristics of the patients at the start of treatment. Patients in poor general condition or with high degrees of pyrexia, high sedimentation rates, or extensive cavitation were culture-positive at the end of two months more frequently than those with more favorable clinical characteristics at the start of treatment. In contrast, the emergence of isoniazid-resistant organisms was related only to the extensiveness of initial cavitation. Therefore, when studying the clinical significance of isoniazid resistance, comparisons should be restricted to patients with the same degree of initial cavitation. Patients with negative cultures at the end of two months showed on the average greater clinical progress after three months' treatment than patients with positive cultures at two months. When standardized for differences in extent of initial cavitation, the percentages with radiographic improvement at the end of three months were 75% for the negative group and 50% for the positive group. There was much less difference in clinical progress at the end of three months between the patients with sensitive and the patients with resistant strains. The percentages showing radiographic improvement were 55% for the sensitive and 46% for the resistant group. Further investigation suggests that even these differences may not be a direct consequence of the development of bacterial resistance, since the radiographic improvements and deteriorations were evenly distributed throughout the three month period. It is therefore possible that relatively poor clinical progress and the development of bacterial resistance are both characteristic of patients with a particular host response or type of disease. Similar studies of the bacterial content of the sputum show a considerable benefit at three months to the sensitive group, 27% having specimens positive on direct examination compared with 65% for the resistant group. Again further analyses yielded no evidence that this difference arose from changes consequent upon the development of resistance. It is concluded that the early disappearance of tubercle bacilli from the sputum is an important sign of favorable progress of patients treated with isoniazid alone. The study of possible clinical disadvantages due directly to the development of isoniazid resistance is inconclusive. Nevertheless, because isoniazid resistance tends to occur in disease that is pursuing a relatively unfavorable course, its development is an adverse prognostic sign. Isoniazid should be given only in combination with suitable dosages of other drugs.

The Sterilization of Blankets with Cetyl Trimethylamine Bromide. R. Blowers and K. R. Wallace. Lancet **1**:1250-1254 (June 18) 1955 [London, England].

It has been shown that patients in hospital quickly become nose and skin carriers of Micrococcus (Staphylococcus) organisms that are resistant to antibiotics. Blankets are largely responsible for the transfer of these organisms from patient to patient and should be washed and sterilized for each new occupant of the bed. The usual method of laundering blankets by a low-temperature wash does not sterilize them, and autoclaving is unsatisfactory, because it produces gross shrinking and felting. Oiling reduces the dissemination of particles from blankets, but there are objections to this process. The authors describe a method whereby blankets are treated with Cirrasol OD, which is an aqueous paste containing about 12.5% of technical-quality cetyl trimethylamine bromide. The consistency of the paste varies with the temperature, but the paste dissolves easily in warm water. Blankets were taken at random from those coming into a hospital laundry from medical and surgical wards. Treatment with Cirrasol produced blankets from which only occasional organisms were isolated. The mean colony-counts on 78 blankets before and after treatment were 194 and 2.6 respectively. In contrast the routine washing procedure was much less effective; the mean counts for 42 blankets before and after washing were 346 and 208 respectively. After treatment with Cirrasol the blankets were of normal appearance and texture and odorless. The authors were able to show that Cirrasol remained in the blankets by shaking them over culture plates sown with Micrococcus (Staphylococcus) aureus. After incubation the growth of the Micrococcus organisms was completely inhibited. Previous work with quaternary ammonium compounds is mentioned.

Use of Isotope-Labelled Red Cells to Demonstrate Incompatibility in Vivo. P. L. Mollison and M. Cutbush. Lancet **1**:1290-1295 (June 25) 1955 [London, England].

In selecting blood for transfusion, it may be difficult to decide whether a reaction occurring in vitro implies that red blood cells will be destroyed in vivo. For example, crossmatching may reveal the presence of a specific antibody strongly active at low temperatures but doubtfully active at 37 C; in other cases all blood samples may react weakly with the patient's serum at 37 C, suggesting the presence of a nonspecific antibody. In such cases there is a real need for a biological test to supplement tests in vitro. By labelling red blood cells with radioactive isotopes, it is possible to measure the survival of very small volumes of blood cells. In investigations reported here approximately 1 ml. of red blood cells were labelled either with the isotope Cr^{51} or with P^{32}. In addition to determining whether the red blood cells of prospective donors are compatible, this method provides a means of discovering more about the action of blood group antibodies in vivo. It was found that P^{32} is suitable as a label when the survival is to be followed for an hour or so; but Cr^{51} must be used when survival is to be followed for days or weeks. When incompatible red blood cells were injected, their elimination followed one of two main patterns: In the first pattern 50 to 100% of the blood cells were destroyed within 10 minutes; blood cells surviving at the end of this period were much more slowly destroyed. This pattern of elimination was seen when blood cells were injected into patients whose serum contained anti-Fy^a, anti-Le^a, or anti-P. In the second pattern the blood cells were eliminated at a steady rate, with a half-period of 20 to 30 minutes. This pattern was seen when blood cells were injected into patients whose serum contained anti-Rh or anti-Kell. In all cases in which red blood cells were rapidly destroyed in vivo, the indirect antiglobulin test was positive in vitro. However, in cases where the serum contained anti-Le^a or anti-P, the cells were sensitized only if incubated with fresh serum. Moreover in these cases it was shown that the reaction of the sensitized blood cells with antiglobulin serum depended not on anti-gamma globulin but upon anti-beta globulin. Some antiglobulin serums were unsuitable for the detection of these antibodies.

INDUSTRIAL MEDICINE

The Value of Lung Biopsy in the Diagnosis of Occupational Pulmonary Diseases. H. S. van Ordstrand, D. B. Effler, L. J. McCormack and J. B. Hazard. A. M. A. Arch. Indust. Health **12**:26-32 (July) 1955 [Chicago].

In 26 of 66 patients on whom surgical lung biopsy was performed in the course of the past five years at the Cleveland Clinic, a question of occupational disease arose on the basis of history, roentgenologic findings, or a combination of the two. In 11 of the 26 patients, the lung biopsy finally proved a diagnosis of an occupational disease, i. e., asbestosis in 1, siderosis in 1, silicosis in 3, and berylliosis in 6. The cases of 2 of these 11 patients that are representative of all of them are reported in detail. In contrast to these 11 patients, a presumptive diagnosis of occupational disease was disproved by lung biopsy in the remaining 15 patients; presumptive diagnosis had been based on suggestive exposure history in 3, on suggestive roentgen-ray picture in 6, and on suggestive exposure history and roentgen-ray picture in the remaining 6; 3 cases illustrating each of these three categories are reported. Surgical lung biopsy is a direct approach to the diagnosis of diffuse pulmonary disease in patients in whom routinely used studies fail to establish an accurate diagnosis. It is a particularly important procedure in borderline cases in which it is otherwise impossible to prove or disprove the presence of an occupational disease.

Comparative Vascular Pathology of Occupational Chest Diseases: Preliminary Observations. G. W. H. Schepers. A. M. A. Arch. Indust. Health **12**:7-25 (July) 1955 [Chicago].

Both the autopsy and biopsy findings in the lungs of persons who had been adequately exposed to industrial dusts, including quartz, iron, coal, talc, gypsum, diatomaceous earth, beryllium compounds, and asbestos, either singly or in combination, showed a diversity of lesions of the blood vessels whose prevalence and extent varied according to the nature of the foreign substances deposited in the lungs, their quantity, and associated infection. The most pronounced effects were on the smaller vessels and comprised cellular and collagenous lesions of the capillaries in the alveolar walls, damage to the intima, muscular coats, and adventitia of the arterioles and venules, and perivascular deposits of pigments, fibrocytes, and macrophages with variable degrees of associated fibrosis. The effect on these small vessels may be to occlude, stenose, and distort them and to create inefficient vascular short circuits. Larger pulmonary vessels may also show damage, ranging from intimal atheroma to medial segmental hypertrophy and collagen degeneration, cicatrical stenosis, and aneurysmal distention. Such vessels may become eroded and rupture. Exploration of the relationship between the silicotic nodule and the vascular system revealed that in silicosis, the vascular damage is an added lesion over and above the specific collagenous nodules, which later may show their own peculiar vascular degenerative phenomena. In anthracosis, siderosis, berylliosis, talcosis, and asbestosis, the perivascular lesion proved to be an integral and indistinguishable component of the pathognomonic pulmonary dust lesion. Specific dust particles or fibers and even asbestos and tremolite bodies may, in most instances, be demonstrated within or in relation to these vascular lesions. In the presence of superimposed infection, particularly tuberculosis, the vascular damage may be disproportionately great. This effect was found to be enhanced if there was associated quartz inhalation. Asbestosis was not observed to follow these rules directly. It is suggested that these vascular changes may be a factor in the genesis of cor pulmonale, though it is not at present established that they may bring about this result in the absence of associated physiological disturbances leading to anoxia.

RADIOLOGY

Comparison of Bronchograms with Bronchial Lesions of Excision Specimens: Value of Thin-Layer Lipiodol. P. Simonin, J. Girard, J.-P. Grilliat and B. Pierson. Strasbourg méd. 6:283-290 (May) 1955 (In French) [Strasbourg, France].

About 300 bronchograms were performed with lipiodol introduced into the bronchi by vaporization. Only 12 cc. of lipiodol at 20 or 40% for two lungs was used. The patients were all tuberculous women between the ages of 18 and 36. No accidents occurred in the series. Of the 279 bronchograms considered suitable for analysis, only 27 could be termed normal. The commonest abnormality seen in the others was moniliform dilatation (210 cases). It is possible to differentiate this entity from dilatations of the ampulla, and they appear to have separate causes. Seven operative specimens were examined in detail, and three types of bronchial lesions were found in them; tuberculous inflammatory bronchitis, discrete caseous bronchitis, and intense caseous bronchitis. From the combined data it can be concluded that pulmonary tuberculosis is accompanied early and in the majority of patients by lesions of the bronchi of the involved segment. Involvement of the elastic fibers is the causal factor in the formation of the dilatations. The changes thus caused are irreversible; the dilatations can be seen on bronchography in patients with cured tuberculosis. All tuberculous patients should be examined by the harmless thin-layer lipiodol method of bronchography. Severe bronchial alterations are an indication for resection of a segment or lobe rather than for more conservative therapy with danger of tuberculous dissemination through the bronchi. In three out of four cases, involvement of the superior lobe is accompanied by a lesion of Fowler's summit on the same side. In patients with bronchial dilatation, one must ascertain whether this is not the result of former tuberculosis before performing surgical intervention, and the operation should be covered by adequate antibiotic preparation.

Effect of Radioactive Phosphorus on Essential Polyglobulism and Increase in the Number of Platelets: Based on 82 Cases. M. Tubiana and J. Gazel. Presse méd. 63:851-854 (June 1) 1955 (In French) [Paris, France].

Among 82 patients with essential polyglobulism, treatment with radioactive phosphorus brought about a decrease in the number of red blood cells and platelets in every case but one. In two patients with increased number of platelets only a decrease was obtained without the production of anemia or leukopenia. P^{32} acts on the hematopoietic system alone and does nothing to diminish the number of circulating red blood cells. Its irradiating effects last about a month after its ingestion. In view of this, one must wait 8 to 10 weeks before judging the results of treatment, or even longer. Great caution should be exercised regarding a second application. The method of administration used by the authors was 0.9 mc. of P^{32} per 10 kg. of body weight given by mouth in the fasting state. The average length of the remissions obtained varied between 5 and 10 months, but the duration is capable of wide variation. Relapses are affected by treatment in much the same manner as the initial attack, but it would seem possible to use smaller doses of P^{32}. When hematological remission is achieved, and sometimes before, the serum iron increases, gastric disorders disappear, and neurological complications are improved. Radiosensitivity to P^{32} is the same regardless of duration of disease, previous therapy, or the number of red blood cells. Treatment with radioactive phosphorus is usually well tolerated; two cases of severe anemia were observed in this series, however.

Two Cases of Brill-Symmers' Giant Follicular Lymphoma Treated with Radioactive Phosphorus. H. Desgrez, G. Ledoux-Lebard, R. A. Guérin and others. Presse méd. 63:954-956 (June 22) 1955 (In French) [Paris, France].

Two women, aged 50 and 80, respectively, were first seen in the advanced stage of follicular lymphomatosis, with generalized lymphadenopathy and serious complications such as serous effusion. Their disease was radioresistant. P^{32} was administered to them by mouth in doses 25% larger than would be given intravenously, to compensate for urinary excretion of the drug. During the period of therapy, the patients had no malaise nor did they suffer hematological disturbances; such incidents could probably not have been avoided if the patients had been treated by teleradiotherapy. After the administration of the first dose of radioactive phosphorus, there was a period of latency of about three weeks before regression of the adenopathy began. Softening of the lesions was noted during this time. The eventual effect of the treatment was excellent and has remained so during a follow-up of 18 months in the younger patient, whose disease was of five years' duration, and two years in the other, whose disease was of eight years' duration. At the beginning of treatment, the doses should be spaced at short intervals and a constant watch kept on the patient's blood. Treatment should be continued after the disappearance of adenopathy. While roentgen irradiation remains the proper therapy for the localized phase of giant follicular lymphoma (Brill-Symmers' disease), the generalized condition is best treated by P^{32}.

The Incidence of Leukemia in Ankylosing Spondylitis Treated with X-Rays: A Preliminary Report. W. M. C. Brown and J. D. Abbatt. Lancet 1:1283-1285 (June 25) 1955 [London, England].

The long-term evaluation of the treatment of ankylosing spondylitis with x-rays has revealed that some of these patients died from leukemia. In recent months an investigation has begun of the death rate from leukemia among patients suffering from ankylosing spondylitis and treated with x-rays. This investigation is being continued under the auspices of the Medical Research Council's working party on leukemia research, and, while its final conclusions will not be reached for some time, the findings to date are felt to be sufficiently important to warrant a preliminary report. A series of 9,364 patients treated from 1940 to 1954, inclusively, has been analyzed and the expected number of deaths from leukemia in this series has been calculated on the basis of the male age-specific death rates from leukemia in England and Wales for 1953. The observed deaths from leukemia have been found to be at least 5 times, and possibly as many as 10 times, the expected number of such deaths, and among patients given more than one course of x-ray treatment the observed deaths are probably at least 9 times those expected to occur. Evidence suggests that patients with ankylosing spondylitis may be unusually susceptible to the development of leukemia, but also it is likely that the incidence of leukemia is appreciably raised among those patients given more than one course of x-ray treatment. Reviewing the above findings in the light of a number of reports in the medical literature, it is concluded that some, if not the majority, of the observed cases of leukemia may be attributable to irradiation. Further investigation is necessary to confirm these findings.

BOOK REVIEWS

Clinical Disorders of Hydration and Acid-Base Equilibrium. By Louis G. Welt, M.D., Professor of Medicine, Department of Medicine, University of North Carolina, Chapel Hill. Cloth. $6. Pp. 262, with 11 illustrations. Little, Brown & Company, 34 Beacon St., Boston 6; J. & A. Churchill, Ltd., 104 Gloucester Pl., Portman Sq., London, W.1, England, 1955.

This timely book deals with problems that in recent years have come to the foreground of clinical interest in medicine and surgery, as well as in many of the specialties. In the first part, which deals with physiological considerations, basic concepts and units of measurement are well defined and various factors influencing the exchange of electrolytes and water, the acid base relationships, and renal physiology are discussed. The much longer second part concerns clinical considerations, including the maintenance and requirements of various metabolites, as well as the parenteral use of fluid, followed by chapters dealing with such specific clinical problems as dehydration, endocrine disorders, acidosis, alkalosis, edema, and acute renal insufficiency. These chapters are extensively illustrated by case histories, and an ample bibliography leads to valuable reference material. The basic principle of the book is the consideration of disorders of electrolyte metabolism as a problem of disturbed equilibrium in general rather than as a specific manifestation of a given disease. It recommends that, in the management of the individual patient, the broader nature of the disturbance not be overlooked. The approach is clinical with the physiological basis well interwoven. Practical diagnostic and therapeutic "pearls" are found throughout the second part of the book. The style is clear but heavy and requires attentive reading. This is the major drawback of the otherwise excellent book, which should be useful for both reading and reference for anybody concerned with these widespread clinical problems.

Prolonged and Perplexing Fevers. By Chester S. Keefer, M.D., Physician-in-Chief and Director, Evans Memorial, Massachusetts Memorial Hospitals, Boston, and Samuel E. Leard, M.D., Assistant Visiting Physician and Assistant Member, Evans Memorial, Massachusetts Memorial Hospitals. Cloth. $5.50. Pp. 248. Little, Brown & Company, 34 Beacon St., Boston 6; J. & A. Churchill, Ltd., 104 Gloucester Pl., Portman Sq., London, W.1, England, 1955.

Fevers of unknown origin present a frequently recurring problem in differential diagnosis. Many of these cases are extremely baffling, and they tend to gravitate into large teaching centers. Although they usually exert a particular fascination for those who have made a special study of infectious diseases, they involve almost every field in internal medicine, and the problem is not systematically approached in textbooks. Thus a volume devoted exclusively to the prolonged fevers is welcome, especially when the senior author is a clinician and teacher of wide experience and international reputation. This book approaches the subject systematically. After a consideration of variations in the normal body temperature, there is a section on the examination of the patient and diagnostic procedures. Thereafter the infectious fevers are discussed in detail, followed by the noninfectious fevers. These latter are associated with tumors, blood dyscrasias, and other conditions. All these subjects are abundantly illustrated by case histories; there is a satisfactory index, and 226 references are listed in the bibliography.

With all this richness of material, it may seem captious to criticize, and yet one puts the book down with a certain sense of disappointment. For example, while the list of diagnostic tests is very full, one would have hoped for more consideration of the order in which these tests are applied. Surprisingly, there is no discussion of the significance of therapeutic agents applied diagnostically. Surely the appraisal of the effects of antibiotics (particularly streptomycin), salicylates, cortisone, chloroquine, and nitrogen mustard looms very large in any study of fevers of unknown origin. Furthermore, rheumatic fever is cursorily treated in just over a page, with no mention of the postcommissurotomy syndrome, while coccidioidomycosis is accorded three pages. The section on drug fever is limited to a consideration of iodism, surely an inadequate treatment of this important field. There is no discussion of sarcoidosis. In a book that describes such rarities as idiopathic familial lipemia and metal fume fever, it is surprising that leptospirosis and cat scratch fever are omitted. On the other hand, much of the book is excellent. The discussions of local septic infections and tumors are particularly good. This volume should be a welcome addition to the library of those interested in fevers.

Canadian Cancer Conference. Volume I. Edited by R. W. Begg, Department of Medical Research, University of Western Ontario, London, Canada. Proceedings of the First Canadian Cancer Research Conference, Honey Harbour, Ontario, June 16-19, 1954. Cloth. $8.80. Pp. 443, with illustrations. Academic Press, Inc., 125 E. 23rd St., New York 10, 1955.

The National Cancer Institute of Canada was founded in 1947, or exactly a decade after the birth of the National Cancer Institute of the United States. This volume records the proceedings of the first (1954) meeting of cancer research workers of Canada supported under its grants, to which were invited a half dozen guests from the United States and one from Denmark. The papers are oriented along the so-called fundamental approaches and are divided into sessions on experimental tumors, tumor-host relations, enzymes, ionizing radiations, and lung cancer. The articles range from thoughtful surveys and a modicum of original data to brief sketchy generalities. The Canadian contributions show some freshness of concept, such as the radiation chemotherapy of Frank and his confreres, and emphasis on certain aspects not well covered elsewhere, such as the lipid metabolism studies of McEwen. The purpose of the book seems to be primarily archival, as a record of the first of what undoubtedly will be a series of meetings. It presents a good cross section study of laboratory cancer research in Canada. Interest in the volume would be limited to the cancer research worker in the laboratory, and the clinician would find it of but little interest. The Academic Press continues to perform an excellent job of publishing biological research. The format, type, and illustrations are up to its high standards.

Sexual Hygiene and Pathology: A Manual for the Physician. By John F. Oliven, M.D., Psychiatrist to Vanderbilt Clinic, Columbia-Presbyterian Medical Center, New York. Cloth. $10. Pp. 481. J. B. Lippincott Company, East Washington Sq., Philadelphia 5, 1955.

This greatly needed book has been well done. Many physicians and all medical students can read it with profit. The material is well organized in four parts, including sexuality in childhood, in the second decade, and in the normal adult, and finally sexual pathology. The author has an attractive style and employs excellent diction for the most part, with only an occasional word or phrase that the purist might question. Typographical errors are so few as to be negligible. It is refreshing to find a book on sexual science that does not repeat the old error of Krafft-Ebing and Max Huhner, attributing the cause of orgasm to the ejaculation of semen or (as the latter claimed) of lubricating fluid from the bulbovestibular glands of Bartholin. It is also cheering to find a psychiatrist not propounding the so-called vaginal orgasm, but stating "the 'failure-to-transfer' theory, i. e., from the child's clitoris to the adult's vagina, much discussed at one time [is] now in decline." Nothing could be truer than the author's conclusion that nonpsychogenic impotence in aging men is most plausibly associated with arteriosclerotic changes in the cerebral, spinal, pelvic, or genitourinary vessels and that "clinical research on, and employment of, those few aphrodisiac substances which have shown promise has been neglected in recent decades, particularly in the United States." Unfortunately the author uses the psychiatric definition of frigidity "in the strict sense, the inability to achieve orgasm during sexual intercourse, often in the presence of affection, desire, arousal, and coital pleasure feelings." This is a paradox

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

and should be abandoned along with the Freudian claim that every woman who cannot have a vaginal orgasm is frigid. Frigidity means sexual coldness, and it is absurd to call the most passionate women frigid merely because they cannot achieve orgasm in normal sexual intercourse. The term "anhedonia cum frigidity" is used repeatedly and is not only an unfortunate hybrid term, but repetitious, because anhedonia (complete lack of sexual pleasure) is a severe type of frigidity. Havelock Ellis's term, hyphedonia, which means lessened sexual pleasure, is not employed at all. The statement that testosterone is probably ineffective where the woman never had experienced orgasm previously is definitely incorrect. There is a tendency to shorten words, as narcism for narcissism, and to combine two as one (spermigration)and there are a few obsolete words such as 'innards' and "fricating,' but the work is a scholarly one. Although 125 authors are listed in a name index, not one had more than a one page reference, not even Havelock Ellis or Alfred Kinsey, though R. L. Dickinson is mentioned twice. There is no bibliography. This book should be welcomed into medical curriculums and in physicians' offices. The author and publishers are to be highly commended for having made it available.

The Chemistry of Micro-Organisms. By Arthur Bracken, B.Sc., Ph.D., F.R.I.C. Cloth. $6. Pp. 343. Pitman Publishing Corporation, 2-6 W. 45th St., New York 36; Sir Isaac Pitman & Sons, Ltd., Pitman House, 39-41 Parker St., Kingsway, London, W.C.2, England; 381-383 Church St., Toronto, Canada, 1955.

This book grew out of a series of lectures "at one of the large London Polytechnics" on the metabolism of micro-organisms. The people who attended the lectures were scientists, but usually they had had little training in bacteriology and biochemistry. Because he tried to reach these people, Bracken's book is an excellent introduction to the subject. There are chapters on culturing micro-organisms in the laboratory, the place of bacteria and molds in nature, the commercially important antibiotics, and the synthesis by micro-organisms of pigments and of various organic compounds arbitrarily discussed (for ease of presentation) in a chapter on aromatic compounds and in one on aliphatic and heterocyclic compounds. The short bibliographies list chiefly British reference books and journals, but they are either common in libraries in the United States or their counterparts can be found easily. The typography and binding are good, and the index seems to be complete.

Clinical Pathology in General Practice. Specially commissioned articles from British Medical Journal, October, 1953, to July, 1954 (fully revised). Cloth. 21s. Pp. 321, with illustrations. British Medical Association, Tavistock Sq., London, W.C.1, England, 1955.

The organization of a national laboratory service in Great Britain made it advisable to provide the general practitioner with a short, simple, nonconfusing reference on clinical pathology to facilitate his contact with the pathologist. A series of short articles that had appeared in the *British Medical Journal* are here reprinted in book form. The authors, who for the most part are leading clinical pathologists of Great Britain, brought the material up to date. The introduction deals with the present organization of the laboratory service in England. The next section discusses technical procedures, mainly those used to obtain specimens for examination. This is followed by the discussion of various function tests, a fairly large chapter on microbiological procedures, a section on hematology—probably the best, a treatise on laboratory procedures in metabolic and endocrine diseases, and a discussion of skin and industrial diseases. The individual articles are authoritatively and well written, but, because of their brevity, much of the discussion is superficial as compared with books used in the United States. The development of the book also explains the uneven and sometimes sketchy coverage. Nevertheless, the pleasant and lucid way of presentation assists in fulfilling the primary mission of the book, to form a bridge between the thinking of the general practitioner and that of the clinical pathologist. For this purpose, it is probably as good as, if not better than, most similar books published in this country. For the second purpose, to guide in the interpretation of pathological reports, the American practitioner will wish a more thorough textbook.

Methods in Enzymology. Volume I. Edited by Sidney P. Colowick and Nathan O. Kaplan. Advisory Board: Britton Chance et al. Cloth. $18. Pp. 835, with illustrations. Academic Press, Inc., 125 E. 23rd St., New York 10, 1955.

Medical scientists must be happy that this four volume treatise is being issued, because the work is the first in English on methods used in the study of enzymes. It will bring together a tremendous amount of information scattered through the periodical literature. Volume I is divided into sections on general methods for separating and purifying enzymes, special methods of preparing and analyzing the various enzymes of carbohydrate metabolism, of lipid metabolism, and of the citric acid cycle. Authoritative descriptions of the best procedures were obtained by asking experts to write about their specialties. The response to the requests must have been phenomenal, because there are 118 contributors to this first volume. Editing was kept to a minimum, but any disadvantages due to the lack of systematic nomenclature are overcome by the indexing of individual enzymes under all their common names. The author and subject indexes seem to be complete, and they are printed in type of a size that is easily read. The book is well printed and is sturdily bound.

Population Genetics. By Ching Chun Li, Ph.D. University of Chicago Committee on Publications in Biology and Medicine: Emmet B. Bay et al. Second edition. Cloth. $10. Pp. 366, with 82 illustrations. University of Chicago Press, 58th St. and Ellis Ave., Chicago 37; Cambridge University Press, Bentley House, 200 Euston Rd., London, N.W.1, England; University of Toronto Press, Toronto 5, Ontario, Canada, 1955.

This volume is an extensive revision of the author's earlier "Introduction to Population Genetics," published in 1948 in Peking. Since coming to this country as a refugee from Marxist genetics, Professor Li, now at the Graduate School of Public Health, University of Pittsburgh, has had ample opportunity to exchange ideas with American and British workers in the field of human genetics. The fruits of these discussions are fully evident in the book. "Population Genetics" is an elementary textbook in what many persons consider a difficult area to understand. Dr. Li makes the subject as clear and as simple as possible. Although the treatment is necessarily mathematical, it is restricted to the level of college algebra and some elementary calculus. With that much background and a knowledge also of elementary Mendelian genetics, no student should have difficulty, since Professor Li has taken great pains to develop each exposition step by step. It is very helpful to have this approach rather than the all too common jumping from peak to peak, leaving the reader to follow if he can.

The subject treated comprises the range of methods applicable in population genetics and in no sense attempts to review the various contributions to the field. Genetic variance and correlation are introduced early and form the basis of further considerations. The first chapters are concerned with the genetics of a single locus in a population, then the complexities of independent and interacting loci are taken up. Systems of mating and inbreeding lead into an invaluable discussion of Sewall Wright's method of path coefficients. Other important topics that are adequately discussed are assortative mating; mutation, selection, and the joint effects of mutation and selection on gene frequencies, subdivision and migration; small populations and effective size; and stationary gene frequency distributions. The author is eclectic in his approach, using the contributions of Wright, Fisher, and Haldane as the basis of the superstructure built on the Hardy-Weinberg equilibrium principle, but he also makes use of many of the contributions to theory and method made by others in this field, including himself. The numerous examples and problems that follow each chapter are especially valuable. Whoever works through these should have a firm grasp of the methods discussed and should be aware of some of the pitfalls that await the foolhardy.

In short, this textbook not only provides a greatly needed elementary treatise for the student but also serves as an invaluable reference work for those who must grapple with human population genetics. Physicians who increasingly are coming to recognize the importance of hereditary factors, especially in the chronic diseases, should find here many useful methods for helping to determine the mode of inheritance of a particular condition, the effects of mutation and selection on its frequency, and the complex interplay of dominance, penetrance, and gene interaction with other genes and with environmental factors that determines the incidence of a trait or predisposition. The books now available that are most comparable to this one are Hogben's "Introduction to Mathematical Genetics" and Dahlberg's "Mathematical Methods for Population Genetics." Li's book, however, is easier to follow than the former and is far more complete in its treatment than the latter. In format this volume is a fine example of the excellent work of the University of Chicago Press, but its high price puts it virtually beyond the purchasing power of the general student.

Ciba Foundation Colloquia on Endocrinology. Volume VIII: The Human Adrenal Cortex. Editors for Ciba Foundation: G. E. W. Wolstenholme, O.B.E., M.A., M.B., and Margaret P. Cameron, M.A., A.B.L.S. Assisted by Joan Etherington. Cloth. $10. Pp. 665, with 227 illustrations. Little, Brown and Company, 34 Beacon St., Boston 6; J. & A. Churchill Ltd., 104 Gloucester Pl., Portman Sq., London W.1, England, 1955.

This volume contains the proceedings of the Conference on the Human Adrenal Cortex held in London in 1954. The participants represented many countries. The book is divided into two parts. The first is concerned mainly with histological and biochemical aspects of the adrenals and corticomedullary relationships and the second with physiological and pathological aspects of the adrenals and hypothalamic and pituitary relationships. Though this volume is primarily concerned with the human adrenal cortex, many of the articles or chapters deal with useful supporting information obtained from animal experiments. Assembled here is the accumulated knowledge of current research on the adrenals in its many ramifications. Though many of the conclusions are incomplete and the results of studies by various workers are contradictory, the lively discussions and arguments among the participants, which are found at the end of each chapter, add much to a better understanding of the complex problems being weighed. A great deal of information not readily available has been brought together under one cover. The book is easily read, is well illustrated, and contains a mine of information. It should prove a useful reference book to workers interested in adrenal physiology and pathology. The clinician should find it useful as background for his clinical studies. The possible areas of usefulness of adrenalectomy and hypophysectomy for the control of certain hormone-dependent neoplasms in man are explored. The chapters on virilizing adrenal hyperplasia and adrenal cortical hyperfunction (Cushing's syndrome) are quite complete.

Modern Health. By James H. Otto, Cloyd J. Julian, and J. Edward Tether, M.D. Cloth. Pp. 566, with illustrations. Henry Holt and Company, Inc., 383 Madison Ave., New York 17, 1955.

Intended for use by high school students, this volume shows evidence of careful preparation to insure attractiveness and ease of use. It is filled with illustrations, many in color. At the end of each chapter, there are a summary, a series of questions for discussion, an exercise in fitting words to definitions, and a true-or-false exercise. All of these devices should be useful to both teachers and pupils at this educational level. At the end are a glossary and three appendixes, including a table of infectious diseases, a list of items for a home first-aid kit, and a listing of National Health Council members. There is also an adequate index. The seven units are presented in a personalized manner, with emphasis on "you." They begin with considerations of personality and personality problems, go on to special senses and the nervous system, and then cover bones and muscles, food and oxygen supplies, protection against disease, and first aid and safety. This volume is intended for use at any level of the high school curriculum. The unit arrangement is such that each can be studied separately, as, for example, in conjunction with work in other courses. Special attention has been paid to keeping the language understandable, and when technical terms are used they are set in boldface, with phonetic spelling. The large number of illustrations adds to the attractiveness of the book, and charts and diagrams are used extensively for graphic demonstration of basic facts. The double column format facilitates reading. The volume should find a definite place in any high school health education program.

The Psychoanalytic Study of the Child. Volume IX. Managing editors: Ruth S. Eissler, M.D., Anna Freud, LL.D., Heinz Hartmann, M.D., and Ernst Kris, Ph.D. Editorial board, United States: Ruth S. Eissler, M.D., et al; Great Britain: Anna Freud, LL.D., Willie Hoffer, M.D., Ph.D., L.R.C.P., and Edward Glover, M.D. Editorial assistant: Lottie M. Maury. Cloth. $7.50. Pp. 369. International Universities Press, Inc., 227 W. 13th St., New York 11, 1954.

Like its predecessors, this volume presents a collection of clinical and theoretical papers on the application of psychoanalytic concepts to the study of early years of life. The firs section consists of an abstract of Anna Freud's public lectur in New York (the 1954 Freud Memorial Lecture) on psychoanalysis and education and a transcript of a day-long discussio conducted with Miss Freud's participation, on problems of i fantile neurosis. The editors have rendered a valuable servic in publishing this material, as both the lecture and the discussio contain ideas that will probably have a lasting impact on psych analytic thinking. The abstract of Miss Freud's lecture unfort nately can convey little of the charm and lucidity of her tal which presented a fresh approach to the role of parents in t development of childhood neurosis. The papers in the seco section range from brief presentations of clinical experiences the treatment of childhood emotional problems to complex t oretical formulations. The last section contains three papers the technique of child analysis. While the contributions nece sarily vary in quality, the general standard is very good. Sin with few exceptions, the papers are written in the technical l guage of psychoanalysis, the chief appeal of this volume will to the various disciplines in which psychoanalytic concepts current.

Healthful Living. By Harold S. Diehl, M.A., M.D., Sc.D., Profes of Preventive Medicine and Public Health, and Dean of Medical Scien University of Minnesota, Minneapolis. With foreword by Morris Fishb M.D. Fourth edition. Cloth. $6. Pp. 529, with 53 illustrations. McGr Hill Book Company, Inc., 330 W. 42nd St., New York 36; 95 Farring St., London, E.C.4, England, 1955.

In this new edition, the shift to the concept that health found where a person can learn about disease and its prevent is given new emphasis. As in earlier editions, Diehl has carr out a creditable presentation of current facts and attitudes the many aspects of health with which the average lay rea is concerned, and the present approach has been broadened e more. Included are discussions that would have been conside far too technical in earlier days, such as those dealing with Rh factor, hormones, antibiotics, and the possible relations of smoking to cancer. A special glossary of medical terms i valuable part of this orientation process. The philosophy of volume is established in the first chapter, which deals with p sibilities of longer life and better health. Chapter 2 summari major health problems, and the third chapter is devoted to men health. Succeeding chapters consider various aspects of fo and nutrition, exercise, the special senses, care of the skin, d ease prevention, narcotics, internal secretions, and sex life a parenthood. The changing age pattern of the population is viewed in a special chapter, and the final chapter provides gu ance on selection of a family physician. At the end there a tables of standard weights, food values of common portions, personal health record, and the glossary mentioned. The book adequately if not profusely illustrated, and large type on high calendared paper makes it easily readable. The extensive ind should be of value to any reader. This volume can be reco mended to the lay public as a means of improving knowledge a understanding regarding today's health problems. The develo ment of radioactive elements and disaster measures are not co sidered. This may be a sensible departure. Seven special fil are available through the publishers for use in connection wi various chapters. These are on emotional health; bacteria; bo care and grooming; the nose, throat, and ear; reproduction; ho mones; and heart and circulatory disorders.

Veränderungen des Thoraxröntgenbildes bei Brustkrebspatienten. Von Doz. Dr. med. Wilhelm Oelssner, kommissarischer Direktor des Röntgeninstitutes der Karl-Marx-Universität Leipzig. Cloth. 21.40 marks. Pp. 164, with 115 illustrations. VEB Georg Thieme, Hainstrasse 17-19 Aufg. C, (10 b) Leipzig Cl (Russian zone) Germany, 1955.

Roentgen examination of the chest has become of extraordinary significance in clinical medicine. In clarifying individual cases, as in serial examinations, it frequently is the decisive diagnostic measure. It is used mainly for primary thoracically localized conditions when pulmonary tuberculosis is suspected or must be excluded. It is rarely used in patients with mammary carcinoma in spite of the fact that repeated roentgen examination of the thoracic cage is invaluable in its treatment and guidance. No previous book has stressed the indications, findings, and results of repeated roentgenographic examination during the treatment of mammary carcinoma, and individual articles touching on these are scattered. Even textbooks on surgery and roentgen diagnosis mention this subject briefly, if at all. No region of the body is more frequently examined with the roentgen ray than the thorax, and, since mammary carcinoma is second in frequency among the malignant tumors of women, this becomes important to internists and chest physicians, who most frequently make such examinations. Every physician should be conversant with the findings of mammary carcinoma, even though he is not concerned directly with this condition. The author's studies cover a period from 1947 to 1952, including more than 1,600 patients with mammary carcinoma. He lists as significant: (1) intrathoracic metastases, (2) severe associated conditions in the breasts that can influence the prognosis and the value of the treatment used, (3) changes resulting from therapeutic measures, and (4) the fact that a lesion is stable. A series of comparative roentgenograms is presented for simplifying differential diagnosis of subsequently appearing symptoms. The book presents the subject clearly for the physician who can read German and offers valuable data on a commonly neglected subject.

Research and Education in Rheumatic Diseases: Transactions of First National Conference at National Institutes of Health, Bethesda, Maryland, November 19, 1953. Edited by Joseph J. Bunim, M.D., Clinical Director, National Institute of Arthritis and Metabolic Diseases. Sponsored by American Rheumatism Association, Arthritis and Rheumatism Foundation, and National Institute of Arthritis and Metabolic Diseases. Published in cooperation with National Institute of Arthritis and Metabolic Diseases, Public Health Service, United States Department of Health, Education and Welfare. Cloth. Pp. 141, with illustrations. Arthritis and Rheumatism Foundation, New York, 1954.

This small volume presents a compilation of papers delivered at the First National Conference of Research and Education in Rheumatic Diseases by the leading investigators and clinicians in this field. The book is divided into four parts. Part 1 deals with the promising areas for exploration and research; part 2 with research and training in rheumatic diseases in the United States; part 3 with medical education in rheumatic diseases; and part 4 with a general discussion of problems relating to rheumatic diseases. The style varies with the individual authors, but every paper is well written. The papers have excellent illustrations, plates, graphs, and bibliographies. The volume contains an authoritative presentation of the basic and clinical research that is currently carried on by prominent investigators. It should prove valuable to all those in the field of rheumatic diseases and stimulating to those contemplating work in this field.

Atlas de chirurgie thyroïdienne. Par Jacques Francillon, chirurgien des hôpitaux de Lyon, et Claude Gabrielle, interne des hôpitaux de Lyon, Lyons, France. Préface de Léon Bérard. Cloth. 3000 francs. Pp. 182, with 134 illustrations par Dr. C. Millet. Expansion scientifique française, 15, Rue Saint-Benoit, Paris 6e, France, 1955.

As stated in the preface, the medical treatment and surgical technique of the diseases of the thyroid are well established. The authors call special attention to the care of the pedicles of the thyroid, the recurrent nerve, and the parathyroids. After evaluation of different incisions and surgical techniques practiced in Europe as well as in the United States, the authors' method of ligation of pedicles and vessels in total and partial thyroidectomy is described and the advantages stressed. Different surgical steps are well illustrated by diagrammatic and anatomic drawings. These are accompanied by short and concise texts. Print and illustrations are excellent. On the whole, the book can be recommended for surgical residents and young surgeons. The experienced surgeons may also pick something of value here and there from the text.

Bone and Joint X-Ray Diagnosis. By Max Ritvo, M.D., Assistant Clinical Professor of Radiology, Harvard Medical School, Boston. Cloth. $20. Pp. 752, with 568 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1955.

The high regard in which Max Ritvo is held by his colleagues in radiology and his friends and acquaintances in surgery, orthopedics, and other medical and surgical specialties is evidenced by the fact that he is on the medical faculties of three medical schools located in Boston, is director of the department of radiology and roentgenologist of the Boston City Hospital, and is associate radiologist of the Beth Israel Hospital. He is a radiologist and scientist who possesses the ability, denied so many fine clinicians, to write exceptionally well. Each sentence is clear and concise. Diction is excellent. The explanations are adequate without being verbose. Most of the illustrations are exceptionally well reproduced. The printing is clear and easy to read. This is a reference book rather than a textbook. The first chapter, headed General Considerations, introduces the roentgenologic techniques of bone and joint diagnosis to the medical student or physician who has not had special training in roentgenology. The other chapters have headings similar to those that would be found in the average orthopedic textbook. In this manner, the various lesions of the bones and joints are taken up in an orderly classification. Hereditary, congenital, and developmental disturbances of the skeleton are grouped together in chapter 2; traumatic lesions in chapter 3; infections in chapter 4; glandular, nutritional, and metabolic disturbances in chapter 5; diseases of the joints and the periarticular tissues in chapter 7; bone tumors in chapter 8; and disease of the spinal canal in chapter 9. A splendid addition to this book is chapter 10, which deals with soft tissue roentgenography. The bibliography is adequate and well selected. As the author states in the preface, the emphasis throughout this book is on the description and evaluation of the roentgenographic manifestations of the diseases and anomalies of the bones and joints. The book is intended primarily for the roentgenologist and for those in training in the field of radiology, but it should be of great value to the orthopedist, the general surgeon who does some bone and joint surgery, and to all who have a real interest in the study of the bones and joints.

Kreislaufregulation: Eine physiologische, pathophysiologische und klinische Studie. Von H. Reindell, E. Schildge, H. Klepzig und H. W. Kirchhoff. Mit einem Vorwort von Prof. Dr. Ludwig Heilmeyer. Cloth. 39.60 marks; $9.40. Pp. 315, with 163 illustrations. Georg Thieme, Herdweg 63, (14a) Stuttgart, Germany (agents in U. S. A. and Canada, Intercontinental Medical Book Corporation, 381 Fourth Ave., New York 16), 1955.

This book summarizes present knowledge of the neural and humoral mechanisms that determine heart rate, blood pressure, stroke volume, and other important variables in the cardiovascular system. A 54-page section describes the various forms of circulatory disturbance involving the vegetative nervous system, especially several forms of collapse. This is followed by a discussion of pain referred to the heart and of anxiety as either a cause or a result of cardiac disease. Case histories are given, and there is an abundance of electrocardiograms. The concluding pages give suggestions for therapy, including tables of drugs and doses. Unfortunately, both generic and brand names are capitalized, so that the one cannot be told from the other, and the doses are given in such terms as tablets and drops. These pages also take for granted that the reader has assimilated all of the preceding pages. This he is not likely to have done, inasmuch as the text lapses occasionally into platitude and at one point goes on for more than two pages without paragraphing. This book should be of interest to cardiologists and physiologists.

QUERIES AND MINOR NOTES

DIATHERMY

To the Editor:—*What is the effect on the skin and other tissues of diathermy treatments used in recommended dosage for various conditions such as rheumatism and back "strain"? Is the effect of diathermy cumulative? How often may it be used without harm?* *M.D., Georgia.*

Answer.—The action of medical electronic diathermy is to bring about the heating of tissues for therapeutic purposes. The local effects of diathermy on the skin and other tissues are those that result from localized heating of tissues. These effects include rises in tissue temperatures and vasodilatation in the area, which result not only in an increase in the caliber of the blood vessels but also in an increase in the number of patent vessels. Thus additional channels are opened in the region with a resulting increase in blood flow through the area. Sweating of the skin is perceived. With the localized heating there is also an increase in metabolic activity of the area. If proper dosages are used, the effects of heat are not cumulative, and therefore the effects of diathermy are not cumulative. Diathermy may be applied as frequently as one would apply heat from any other source provided of course that excessive dosages were not used with each application. It must be realized that in the treatment of rheumatism and back "strain" diathermy provides only heat, which in many instances can be considered to constitute only part of the treatment of these conditions.

FLATFOOT IN CHILDREN

To the Editor:—*What should be done for a 21-month-old child who is markedly "pigeon toed." The child is able to walk well but frequently stumbles and falls. There are no other visible abnormalities.* *M.D., New York.*

Answer.—The first thing that must be ruled out is a talipes adductus, which is a true congenital anomaly. The foot is in the adducted position and resists manual correction. Such a foot must be corrected in a manner similar to the treatment for the congenital clubfoot (talipes equino varus). Occasionally the foot turns in due to a deformity of the metatarsal bones (so-called metatarsus varus). This gives rise to a pes adductus deformity and is a congenital anomaly that requires gradual correction by means of casts or surgery. Most intoeing, however, is on a physiological basis. It is an instinctive attempt of a child to correct flatfoot. Correction of flatfoot will obviate the "pigeon-toed" walking. Correction of flatfoot in children is discussed in "Diseases of the Foot," by Emil D. W. Hauser (Philadelphia, W. B. Saunders Company, 1939).

SLIDING HERNIA

To the Editor:—*What may be the cause of a sliding hernia? What are the impressive diagnostic procedures that may reveal the presence of a sliding hernia in the absence of mechanical ileus? What operative procedure offers the most promising results in repair of sliding hernia?*
J. V. Waitkunas, M.D., Woodhull, Ill.

Answer.—The usual hernia is contained in a sac of parietal peritoneum protruding through a defect in the abdominal wall. In a sliding hernia, a partially retroperitoneal viscus slides through the defect to form part of the wall of the sac. A common variety occurs when the parietal attachment of the cecum or sigmoid is drawn into the sac by traction on the parietal peritoneum by the increasing size of an indirect hernia. Another type results from an extraperitoneal organ being pushed through a defect in the abdominal wall just peripheral to it. This type of hernia may be extrasaccular. The usual site is the bladder thrust through Hesselbach's triangle and the external inguinal ring. The surgical import of sliding hernia lies in recognition of the condition before the viscus or its blood supply is injured during herniorrhaphy. The sliding viscus is reduced, and the neck of the sac, if any, is closed prior to its amputation. The defect in the abdominal wall is repaired. There are no diagnostic signs peculiar to sliding hernia. Successful herniorrhaphy depends on astute appraisal of the anatomic and structural situation disclosed at operation and repair of the defect as dictated by the individual circumstances.

POSSIBLE CEREBRAL THROMBOSIS

To the Editor:—*A man, aged 81, previously in good health except for moderate hypertension and a tendency to belch gas after eating, suddenly had a severe right-sided headache not accompanied by vomiting or dizziness. He had an irregular temperature ranging from 98 to 101 F, and there was numbness of the hands and feet. Articulation, memory, and judgment were poor. On admission to the hospital, the patient's red blood cell count was 5,130,000 per cubic millimeter, white blood cell count 5,700 per cubic millimeter, hemoglobin level 16 gm. per 100 cc., and sedimentation rate 56 mm. the first hour. The urine and electrocardiogram were normal. Blood nonprotein nitrogen was 43.5 mg. per 100 cc. A spinal tap was done, after which the headache was suddenly relieved. Cloudy fluid dropped from a no. 20 needle at the rate of 120 drops per minute, the white blood cell count was 1,588 per cubic millimeter, and there were no red blood cells. Polymorphonuclear leukocytes were 90%, and lymphocytes were 10%. Culture was negative. Protein level was 270 mg. per 100 cc. Globulin negative sugar was 14 mg. per 100 cc., and the colloidal gold curve was 5541000000. Blood and spinal fluid Kahn tests were negative. After six days the spinal fluid white blood cell count was 570 per cubic millimeter, with the same proportion of polymorphonuclear leukocytes and lymphocytes as formerly. The numbness had disappeared. His ability to pronounce words was better. The fever persisted. The blood pressure, while the patient was in the hospital, remained between 180 and 160 mm. Hg systolic and 90 and 100 mm. Hg diastolic. If further procedures can be suggested to arrive at a diagnosis I would be glad to have them.*
Louis LeFevre, M.D., Muskegon, Mich.

Answer.—It would appear from the information supplied that this man experienced cerebral thrombosis, but its exact location cannot be stated. In favor of the vascular nature of the lesion are his arterial hypertension, the abruptness of onset, the absence of evidence of materially increased intracranial pressure, and the rather prompt improvement, apparently, without the use of antibiotics or other chemotherapy. The findings on examination of the cerebrospinal fluid are consistent with an infarction that involves either the ependyma or the pia, since a predominantly polymorphonuclear pleocytosis is seen in such cases, together with the increase in protein. The 14 mg. per 100 cc. of sugar in the cerebrospinal fluid strongly suggests bacterial infection, but since the culture of the cerebrospinal fluid was negative, presumably without antibiotics having been given, meningitis would seem to be most unlikely. It would help to know whether the sugar level in the cerebrospinal fluid was low in both specimens. In any case, a third puncture should be done, the pressure accurately measured, the sugar content determined, and the fluid cultured. Of course, neurological reexamination must be frequently carried out. In view of the patient's improvement, it would appear safe to continue the

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

present management pending new information or developments, but the addition of suitable antibiotic therapy could do little harm.

LOSS OF TESTIS

To the Editor:—*A 65-year-old man suffered a traumatic injury of his left scrotum requiring removal of the left testis about a year and a half ago. Following the operation, the right testis became atrophic. Three days postoperatively he began to develop hot flashes and sweats. At that time he was assured that these would be temporary and of short duration and was started on male hormone therapy. Since that time he has continued to have hot flashes and sweats day in and day out occurring about one-half to an hour apart, many times awaking him at night because his pajamas become drenched with perspiration. Even on the coldest winter days the sweat will stand out on his nose and forehead. He has been given long courses of male hormone by injection and by mouth. In addition he has received thyroid and vitamin B complex and has had a long course of probanthine. In all other respects, he is in completely good health and has no other complaints. There are no other unusual physical findings except as related to his absent left testis and atrophic right testis. What would you recommend in this case?*

William S. Keenan, M.D., Rockford, Ill.

Answer.—In the case of a 65-year-old white male who suffered the loss of function of his left testis a year and a half ago due to a traumatic lesion, surgery apparently was applied for removal of the remnants of the left testis and cord, because it is stated that, following the operation, the right testis became atrophic. This would imply that the right testis has also been injured, or the blood supply interfered with, and that atrophy of the testis resulted thereafter. The postoperative development of hot flashes and sweats suggests that perhaps the right testis may have been atrophic prior to the removal of the injured left testis, because this is a very short period of time for endocrine deficiency imbalance from a vasomotor point of view to appear. It was very foolish to assure this patient that these flashes and sweats would be temporary, because one is never sure after castration as to the exact vasomotor and emotional factors that will result. Since the patient has not improved with administration of male hormone and has received vitamin B and probanthine—the reasons for the latter not being clear to me—this suggested that, in addition to a maintenance dose of male hormone, the patient also be given estrogens, which may very rapidly control the hot flashes and sweats. Since one never knows the percentage of estrogen and androgen that is the result of testicular and adrenal function, it is always well to replace (unless one is treating cancer of the prostate) the deficiency of female hormone as well as male hormone. In this case it is suggested first of all to correct the idea that one is sure that these flashes can be controlled, and, secondly, give the patient female hormone in various quantities, starting, for instance, with 1 mg. of stilbestrol or its equivalent every day, then every other day, and then, perhaps, once or twice weekly.

REMOVAL OF PROSTATE

To the Editor:—*A 53-year-old man, having some urinary disturbance, consulted two urologists, each in a different city. He was told he had an adenoma of the prostate. One advised a suprapubic removal; the other a transurethral resection. The patient is in a quandry as to which type of removal would be best for him. He is in good physical condition except for a chronic bronchitis and tachycardia, both of which are probably from the use of tobacco. Is there more chance of recurrence when doing a transurethral resection?* *M.D., Ohio.*

Answer.—It would be impossible to give an intelligent reply to this query as to which type of operation would be best suited to his individual case. It would depend a great deal on the exact size of the gland, all of the other considerations involved, how much tissue should be removed, what the condition of the upper urinary tract is, what the domestic and sexual outlook of the patient is, and who is going to perform the procedure—will he be an expert prostatectomist through open surgery or one who has had a great deal of experience and possesses the skill to do a proper transurethral resection. These are all criteria that would influence such a decision. There is the chance of recurrence after a transurethral resection, especially in a patient 53 years of age who may continue to live for 20 or 25 years beyond the time of the procedure, but there is also always a remote chance of recurrence following enucleation. The chance of recurrence in the hands of a good operator is not believed to be of major consideration.

FLEXION OF KNEES IN HOSPITAL PATIENTS

To the Editor:—*It is the custom of the hospital I am associated with to place the knee gatch up so that the knees are kept flexed in bed. I have been taught that this promotes venous stasis and thrombosis. Inasmuch as the above is standard procedure at my hospital and taught to the nurses I would like to change it but need the support from other places.*

M.D., New York.

Answer.—Twenty-five to 30 degrees of knee flexion relaxes the pull of the hamstring muscles, and, if the patient is properly positioned, should not cause any compression or constriction of the extremity, producing venous stasis or thrombosis. The so-called Williams' position for treatment of patients with acute lumbosacral pain includes this knee flexion. There is no report that would indicate that the thousands of patients so treated every day develop any more phlebothrombosis, or have any more venous stasis, than do patients whose legs are kept straight. In either event, it is advisable to urge and require movements of the legs at frequent intervals. The use of Ace bandages in the older patients or for any patient who has evidence of poor venous circulation is certainly advisable.

TO HASTEN EPITHELIZATION OF BURNED AREA

To the Editor:—*In 1953 a 70-year-old man was burning brush, his clothes became ignited, and he suffered first, second, and third degree burns of hands, arms, legs and genitals. He refused hospitalization and skin grafting. I treated him with Vaseline pressure dressings to extremities until July, 1954. By this time the upper extremities and genitals were healed. On the right leg just below knee there is a band of granulation tissue 5 in. wide extending around the leg onto the calf. On the left leg there are only two areas of granulation tissue the size of a quarter and a dime. To these areas one member of the family applies twice daily a 2% solution of gentian violet with cresol, 0.35%. While the best we can hope for is scar tissue, I would like to know how to hurry this process along.*

M.D., Massachusetts.

Answer.—To hasten the process of epithelization of the granulating area referred to, it is suggested that silver nitrate on a stick (cautery) be applied once a week (silver nitrate, 75%, potassium nitrate, 25%) to the granulating surface. This procedure should cut down the overgrowth of granulating tissue and permit the epithelial cells to grow over the part.

COMPLICATION FOLLOWING EYE INJURY

To the Editor:—*A patient with an intraocular foreign body developed supraorbital neuralgia as a complication about seven days after the removal of a piece of steel. This was the first time I had seen this complication in any eye case. 1. Is this complication rare in any eye case? 2. How often does it occur in eye cases generally and in intraocular cases specifically?* *W. G. Hayden, M.D., Toms River, N. J.*

Answer.—Following serious injury to the eye, such as contusion, abrasion of the cornea, penetration of the globe by a foreign body, and surgical procedures, complications due to the injury frequently appear in a few days or months or even years. Among the most serious complications are pain in and about the injured eye, due to inflammation of the uveal tract, and secondary glaucoma. Uveitis following removal of intraocular foreign bodies is likely to be the rule rather than the exception and frequently exists in a low grade that escapes detection. Evidences may be detectable only by close examination of the anterior segment of the eye with the biomicroscope. The state of the pupil is not a dependable indication of the presence of uveitis, as it may be well dilated and fixed as a result of the entrance of the foreign body, the operation for removal, or the instillation of a mydriatic. The severity of the uveitis is sometimes much greater than the appearance of the eye would indicate, and supraorbital neuralgia is not uncommon as the dominant symptom. A sequel to uveitis in traumatized eyes is secondary glaucoma. In these cases either the pupil has become blocked (iris bombé) or the spaces in the filtration angle have been sufficiently closed to cause a rise in tension. Supraorbital pain in such a case may be the result of the glaucoma, but, in the presence of mixed conditions of the eye, in which either one could cause the pain, there is little reason to try to differentiate. The action of drugs is not normally specific in such cases. Atropine for the uveitis is indicated but may be contraindicated by the secondary glaucoma. Likewise, miotics may be useless or even harmful. In the absence of infection, antibiotics are not indicated, and cortone compounds have no predictable effect. The neuralgia may be severe and persistent, justifying the use of sedatives in doses required in critical pain. Probably the best aid in differential diagnosis and in treatment is artificial fever produced by intramuscular injection of 5 to 10 cc. of boiled milk or by typhoid vaccine to produce a rise in temperature to 101 to 103 F within three or four hours and repeated every other day until symptoms of uveitis disappear. Statistics are not available on the frequency of supraorbital neuralgia following removal of foreign bodies from the eye, but it may be expected in any case and undoubtedly occurs more often than records show, although it may not always be attributed to the injury.

TELANGIECTASIA IN A CHILD

To the Editor:—*I recently saw a 5 year 9 month old child with telangiectasia that apparently began when the child was about 3 years of age, appearing on the face and lower arms. These lesions have become more numerous, spreading to the lips, across the shoulders onto the lower extremities, and to a lesser extent on the body. The lesions are mainly spider-like and blanch on pressure. There are hundreds of small areas of skin atrophy, especially on the arms around some of these lesions. There is no family history of such a disorder. Physical examination of the child is otherwise essentially normal. Laboratory studies including complete blood cell counts are perfectly normal. Is there any treatment that would benefit this child's condition?* *M.D., Tennessee.*

Answer.—Multiple spider-like telangiectasia is not apt to occur in a child of this age. The combination of telangiectasia and atrophy is typical of xeroderma pigmentosum in a child whose skin does not pigment readily. The parents are often blood relatives, and the child shows abnormally strong reaction to exposure to ultraviolet rays. The erythema is prolonged and is followed by atrophy, telangiectasia, and hyperpigmented (post-inflammatory melanosis) macules. Keratosis develops in which cutaneous carcinoma and, rarely, melanoma appear. The only satisfactory treatment is protection from ultraviolet irradiation.

TUBERCULOSIS IN WATER BUFFALO

To the Editor:—*Since coming to India, I have heard it said by many that water buffalo do not contract tuberculosis whereas cows do. Therefore buffalo milk is considered safe. None of the cows are tuberculin tested. Is it true that water buffalo do not contract tuberculosis? Also, what is considered a safe time to boil milk to make it safe to drink?*

Albert C. Holt, M.D., Bombay State, India.

Answer.—Water buffalo are not resistant to tuberculosis. Of 500 inspected in abattoirs in India in 1944, 25 showed infection and Mycobacterium tuberculosis was recovered from lesions in 13 animals. To destroy such pathogenic bacteria in milk it need not be boiled. It may be heated to 142 F to 145 F for 30 minutes or 160 F for 15 seconds.

CONDYLOMA ACUMINATUM

To the Editor:—*I would like information on the source of infection of condyloma acuminatum of the female genitals. Are such viruses transmitted through sexual contact only? In persistent urinary meatal condyloma, is there any better treatment than the use of Podophyllin or fulguration?*

Herman V. Platt, M.D., Santa Monica, Calif.

Answer.—For information on the source of infection, there is an article on condyloma acuminatum by Raymond C. V. Robinson in the *American Journal of Syphilis, Gonorrhea and Venereal Diseases* (38:609, 1954). There is no better treatment than Podophyllin or fulguration.

SUDDEN CARDIAC ARREST

To the Editor:—*With reference to the section Queries and Minor Notes, "Sudden Cardiac Arrest" in* The Journal, *July 2, page 800, a third mechanism, inefficient contractions of the respiratory muscles, might well be added to the two mechanisms listed for producing sudden cardiac arrest following electric shock treatment, namely, heart strain and neurogenic disturbances of the medullary cardiac centers. The inefficient contractions occurring during the convulsions produce hypoventilatory complications, the most serious of which leads to hypoxemia. This situation is further impaired with the simultaneously increased oxygen utilization by the convulsing musculature, and the resulting hypoxemia, alone or with other mechanisms, can also produce cardiac arrest. R. J. M. Steven and others (Anesthesia for Electroconvulsive Therapy,* Anesthesiology **15**:*623-636 [Nov.] 1954) report a technique designed to reduce hypoxemia even when muscle relaxants are used to diminish the violence of the electroconvulsions. However, regardless of the technique used, recognition of this third mechanism will prompt the frequent prophylactic use of oxygen and assisted or artificial respiration in order to prevent cardiac arrest.*

Harold Davis, M.D.
St. Luke's Hospital
San Francisco.

To the Editor:—*In Queries and Minor Notes* (J. A. M. A. **158**:*800 [July 2] 1955) in response to a question concerning treatment of cardiac arrest following electric shock treatment, certain ill-advised recommendations were made, such as: "The ideal way of dealing with cardiac arrest is the use of a cardiac pacemaker." It is further stated that if such an apparatus is not available, strong mechanical stimulation on the chest and various intravenous and intracardiac injections should be tried. Strong objection should be raised to this ineffectual approach. Cardiac arrest following electric shock should be reversible in a great majority of the cases—but requires immediate direct treatment. The oxygen system must be restored without delay (Beck, C. S., and Rand, H. J., III: Cardiac Arrest During Anesthesia and Surgery,* J. A. M. A. **141**:*1230 [Dec. 24] 1949; Brofman, B. L., and Perez-Alvarez, J. J.: Successful Treatment of Cardiac Arrest,* A. M. A. Arch. Surg. **69**:*12 [July, pt. 1] 1954). Oxygen must be delivered to the lungs by positive inflation via an intratracheal tube; circulation must be restored by effective massage of the heart. This can be accomplished only by opening the chest and exposing the heart. If ventricular fibrillation is present defibrillation must be performed before a coordinated heartbeat can be restored. No time can be wasted on such procedures as hooking the patient to an electrocardiograph, repeated auscultation or blood pressure recordings, or striking the chest wall. An electronic cardiac pacemaker has no immediate application in this situation. Its primary use is in Stokes-Adams attacks associated with complete heart block. The time wasted in the useless functions suggested in response to this query would probably preclude successful resuscitation without residual damage to vital organs.*

MEDICAL EDUCATION LOOKS AT GENERAL EDUCATION AND THE UNIVERSITIES

Ernest E. Irons, M.D., Chicago

The invitation to participate with a representative of the law in a discussion in which the professions look at general education is an honor that I deeply appreciate. Borrowing a term from my legal colleague I am happy to "present the case" for medicine. In keeping again with legal terminology, I presume I should "qualify myself" as a witness as best I can. I taught in country schools, then in a high school, later in the university, and finally in medical school, where, in addition to other duties, I enjoyed and suffered the vicissitudes of dean of faculty and students for 13 years. In my undergraduate years at the University of Chicago, I was much influenced and stimulated by personal educational contact with its great first president, William Rainey Harper. The continuation of my education has included 50 years of medical practice and the observation of educational results in medical students and on their medical careers. For professional educational theory, however, I must defer to my university colleagues.

EDUCATION

The educational problems of the three professions of the ministry, law, and medicine obviously differ in technical content, but it would seem that their fundamental educational requirements are essentially the same. The ministry and medicine have much in common; originally they grew up together. They share in the tragedies of sickness and death and in the guidance of parishioners and patients along lines of conduct that will avoid the penalties of infractions of moral and medical principles. The law and medicine are closely related in dealing with social and personal problems of individuals, with the administration of justice, and with medicolegal regulations developed through centuries of experience.

Education has been described as the "taking on of the arts and sciences, and of moral attitudes which make up the fabric of civilization." In this process educated people should acquire an appreciation of values, the ability to think, and the ability to see the relations of values to each other in human living. Unfortunately, as George Vincent put it, many people do not think; they merely rearrange their prejudices. The Harvard report on the goals of education stated the problem well. "The aim of education should be to prepare an individual to become an expert both in some particular vocation or art and in the general art of free man and citizen. Thus the two kinds of education, once given separately to different social classes, must be given to all alike. . . . The aim of general education may be defined as that of providing the broad critical sense by which to recognize competence in any field." The observation of Henry Morrison that "we do not learn what to do, but rather become the kind of people who will know what to do" is well exemplified in the quality of performance of physicians and of those in the other professions. How does the change to which the Harvard report refers relate to medical education, particularly to our current problems?

EARLY MEDICAL EDUCATION IN AMERICA

Some reference to the history of medical education in America will clarify the successive changes that have now culminated in the present close relation of medicine to other university disciplines. In the beginning, medicine had been closely associated with the priesthood. Its principal elements were a combination of superstition, empiricism, and observation. Out of observation and curiosity, in medicine as in other branches of learning, came science, which has grown in relative importance until superstition has been largely eliminated and empiricism is giving way to reliance on fact. Medicine, together with law and theology, developed in the monasteries and then in the universities—Padua, Montpellier, and Paris—and later in others, including Leyden, Oxford, and Cambridge. In 1765 when the first American medical school was founded in Philadelphia by John Morgan and William Shippen, students of medicine in America, as also in England, qualified by service as apprentices to established physicians; the more ambitious journeyed to London, Paris, Leyden, or Edinburgh to continue their medical studies. The Philadelphia school, patterned after Edinburgh, stated among its requirements for admission to candidacy that "such students as have not taken a Degree in Arts . . . satisfy the trustees and professors of the college concerning their knowledge of the Latin tongue and in such branches of Mathematics, natural and

---

Read before the Centennial of Michigan State University, Lansing, Mich., April 27, 1955.

experimental Philosophy as should be judged requisite to a Medical Education. . . . It is further required that each student, previous to obtaining a Bachelor's Degree, shall have served a sufficient apprenticeship to some respectable practitioner in Physic, and be able to show that he has a general knowledge in Pharmacy." These requirements remained in force until the occupation of Philadelphia by the British in 1777.

Later, as medical schools increased in number, the college course, which had been at first an adjunct or review in completion of a serious medical apprenticeship, gained in importance while the quality of the apprenticeships deteriorated and offered only a nominal opportunity to the students, finally becoming merely a perfunctory item of a year's credit on the college course. In the absence of examining boards, independent of the schools, a school diploma was accepted as scholastic qualification for license to practice medicine. Competition among the increasingly numerous schools encouraged low standards of admission and performance, without the salutary control of a competent and independent examining authority. But despite the later separation of licensure from educational function, medical schools continued to increase to the number of 162, largely in response to the needs of a rapidly growing population. Some were poor, some good, and some affiliated or integrated with universities. Such were the conditions up to the decade of drastic reform in medical education at the beginning of the 20th century. Now there are 80 medical schools. All but six are now parts of universities, and all are of approved legal and instructional quality. Thus medical education in America, which began under university aegis, has, after a century of wandering, come back to university guidance and standards. The problem now is how medicine may further improve the quality of medical education and promote good citizenship by availing itself of the scholarly influence of the universities.

MEDICINE—AN ART OR A TECHNOLOGY

Medicine is an art as well as a technology. The growth of science, applied in myriad ways in medicine, has made possible marvelous advances in the diagnosis, treatment, and prevention of disease. In this achievement, medicine in its educational program has turned more and more to science and has frequently neglected cultural subjects that contribute to the art and humanitarian facets of medical practice. With the return of medical schools to closer university association, this fault, which grew during their century-long separation from universities, is now slowly being corrected. A sound technology based on science is requisite to medical progress, but good efficient professional medical care includes the heart as well as the head. Multiple acquisitions of bits of applied sciences have created another difficulty by favoring the formation of many subspecialties, which are taken up by young physicians before they have acquired by experience a broad foundation in clinical practice and a more mature judgment in dealing with human affairs and impulses. The picture of the patient himself is obscured by the shadow of a minor item administered by a technologist. Increase in scientific facts applicable to the problems of medicine has led to so great a multiplication of specialties and subspecialties that increasing numbers of physicians who are highly skilled in some difficult but relatively narrow special field have failed to acquire or appreciate the larger objectives of medicine in the care and cure of the sick patient. This trend toward surrender of a profession to a technology calls forth well-merited criticism of the medical profession, often expressed by the phrase "the passing of the family doctor."

While the younger physician must conserve his time and strength if he is to continue to grow in medicine, he should not forget that the greatest professional satisfaction in the practice of medicine is the close patient-physician relationship of the family doctor. The better-prepared physician of the future will keep abreast of th advances in technology but will still retain the ideals o medicine; the family doctor will not have passed—h will have improved. Medicine is not alone in this extreme technological departmentalization. In universitie also the tremendous increase in scientific interests in th past 50 years resulted in vast university expansion. I making innumerable new appointments, university a ministrations have found it difficult or impossible secure men who "combined their specialties with a sen of the relevance of general culture to all research." A the same time the university specialist, even when h is not a specialist in the natural sciences, has concern himself so exclusively with methods and technolo that the personal, the human side of life is often ne lected. The increasing incorporation into medical pra tice of new scientific knowledge has thus weighted me ical educational interests in favor of science and lessen the apparent importance of cultural subjects such as h tory, philosophy, languages, and literature. This do not prepare the medical student to know his future p tients as men and women. It inclines him to treat disea as a purely technical problem. Some university educ tors even maintain that "times have changed" in educ tion and that no longer should the student be obliged spend his energies in study of subjects not directly co cerned with science. This narrow concept proposes conserve present time and effort at the expense of futu general quality; it accepts the attainments of a tec nology but discards the dedication of a profession.

Premedical cultural education contributes to ment maturity and prepares the student to deal more effe tively with the great masses of scientific data that later h must fit into his medical preparation for his life work. A this point "how to learn" is more important than "wh to learn." A general cultural education not only is one his most important immediately useful tools but also a source of professional effectiveness in the art of me icine and affords entrance to the cultural satisfaction later life. It is evident that not all prospective physicia will be willing to devote more than the minimum tim requirement to cultural subjects, and perhaps some them are well advised to get on with their technologica studies. Not all students can be passed through the sam mold. In subsequent years some of the more pragmatically inclined students will regret their haste, and a fe may even fill in some of the educational gaps and com to enjoy the intellectual satisfactions they would otherwise miss.

QUANTITY AND QUALITY

The "headlong growth of knowledge" and the "extension of education downward" have created new problems in university education as well as in secondary education and in medicine. The increase in population of cities and more recently of suburban communities has so greatly increased the school population that school authorities have difficulty in providing both school houses and qualified teachers. The demands of quantity have interfered with quality. It would appear that some universities also have at times suffered lapses in quality, the causes of which in part have arisen from inferior training of supposedly qualified students in secondary schools and from the popularity of the college idea in the minds of the public and of many students who are not really interested in acquiring a cultural education. The resultant lowering of the average quality of students through this dilution must be a painful experience to scholarly members of those faculties. The results of relaxation of such cultural educational standards as had been attained in medicine were well demonstrated in the last war. Besides the distraction and disturbance of general thinking, medicine suffered through the abbreviation of premedical preparation, the acceleration of the medical course with its condensation of four years into three, and the concentration of internships and residencies. To those of us who were faced with the medical emergency of the armed forces, the acceleration of the medical educational program seemed a necessary and therefore a permissible compromise to which we subscribed as a wartime measure, but we were well aware that educational standards were being sacrificed to immediate necessity.

In his hurried acquisition of prescribed facts, the student lacked time as well as strength for collateral reading; his jaded mind failed to respond to such impulses of curiosity as he might fortunately experience. The superior students felt this keenly; the weaker students never knew what they missed. This wartime temporary step backward in medical education, the ill-effects of which still linger, emphasizes the necessity of a peacetime further advance in cultural education at university levels.

SCIENCE AND THE HUMANITIES

In medicine, even though the medical schools are now largely under the technical guidance of universities, science has come to overshadow the cultural aspects of education. True, it is through the application of modern science, which itself has a definite cultural value, that medicine has achieved its vast accomplishments of the past 50 years in prevention and cure of disease and the lengthening of the span of human life by 20 years. But this prolongation of life in turn has produced new economic, social, and medical problems such as the possible postponement of obligatory retirement age and the medical care of the aging, which will only be solved by broadly educated men and women. The physician occupies a unique place in his community. He cares for the physical and mental ills of his patients, and as family advisor he is requested to pass judgment on a multitude of matters not directly related to medicine. He should be prepared also to accept leadership as a citizen in his community and, as opportunity presents, in the larger affairs of the nation.

In our country for the past 20 years assaults on our national ideals, inaugurated still earlier, have centered on medicine, already selected as a vulnerable point of attack in nations of Europe by socialistic and communistic forces. It is not without significance that programs in education sponsored by communist elements have recommended specialization at an increasingly early age. British medical educators now note with concern the ill-effects of socialized medicine on the motivations and quality of student applicants. In this reversion to inferior standards a "desire for achievement is being replaced by a search for security." To maintain medical standards, which are a significant part here of our national standards of living in the democracy of our republic, the prospective physician must have a basic knowledge of history and literature and economics, a broad and sound philosophy, and a willingness to work. We recall the words that MacMichael attributes to Radcliffe, the great English physician, philanthropist, and benefactor of Oxford, in the story of "The Gold-Headed Cane." Radcliffe said, "For as I have grown older, every year of my life has convinced me more and more of the value of education of the scholar and the gentleman to the thoroughbred physician." Radcliffe's 17th century comment has even greater significance at the midpoint of the 20th century. The ideal physician should be a cultured gentleman. This has nothing primarily to do with wealth; rather it is an expression of education, broad culture, character, kindliness, emotional stability, and inborn consideration for others. These qualities will serve well the public and the physician in his practice, just as politeness and consideration for others in driving a car on the highway will avoid many traffic accidents.

EDUCATION AND MEDICAL RESEARCH

The amazing growth of scientific knowledge, to which medicine owes much of its own achievements in the amelioration of suffering and the saving of lives, has come through the free mental activity of men trained to think rationally and at the same time to give free rein to their imaginations. While entirely new concepts occasionally necessitate an extensive rearrangement of previously held notions, the progress of today rests largely on the labor of yesterday. The man who proposes to engage in research requires first a broad general education in order that he may develop an ingrained critical sense, the first line of defense against wild and unworkable theories. Some men never acquire this discriminative ability, nor have they the diligence to learn what has already been done, and they fall victims to and sometimes become protagonists of procedures that in the end do harm to the cause of medical science. Some even deserve the cynical comment of a celebrated wit: "If you steal from one author, it's plagiarism; if you steal from many, it's research." Manifestly this remark is unfair to good research. It does, however, characterize certain reports that pose as research. Inquiry usually will disclose gaps in the early education of such authors.

The benefits of fundamental research, the result of private expenditure, have been so overwhelmingly demonstrated that research is now confronted with a new problem, that of withstanding popularity. It is assumed that since the value of research to the nation has been so outstanding, more research will be still better, and the government should invest millions to supplement previous privately supplied funds and go in for the purchase of research in a big way. Varying opinions are held as to the advisability of government-subsidized research; some hold that government funds are needed to reinforce private sources now being exhausted by heavy tax burdens, and others maintain that the entry of government funds into the research field will itself discourage further contributions from private sources. But more important than these questions is that of the method of utilization of funds. Imagination and ideas cannot be grown to order; they come from unsuspected places. After the initial idea or concept is born, collateral lines of approach must be explored patiently and often without positive result. The scientific method cannot be forced, nor will the provision of funds by the officials of the state or of foundations for specific purposes of their own devising bring it forth. And so, research must be free—free from the demands of today or tomorrow. Such freedom can be best realized in universities; workers must be under no compulsion other than the inner driving force of their genius. If government funds are to be used to advantage, they should be under the direction of universities, and especially of individuals in them who have already demonstrated their ability to utilize their own funds, free from any governmental obligation or political interference, inspired only by a love of truth.

PERSONAL RESPONSIBILITY

Under recent popular political leadership now fortunately on the wane, many people, especially of the younger generation, have been led to believe that they can avoid personal effort and get help by looking to government. They have been taught to "demand their rights" with no word as to their own responsibilities as citizens. They do not realize that they and their fellow citizens are the government. Humanity demands local and state help for the unfortunate and needy; needy students also should receive help to supplement their own efforts. But they and some of their elders might well consider the fable of the frog.

A frog found himself in a deep rut in the road and made a number of unavailing hops to get out. A rabbit came by, heard the frog's story, and volunteered to get a ladder. When he came back with the ladder, he found the frog sitting on the grass beside the road and asked him how he did it. "O," said the frog, "a wagon came along and I just had to get out." Now as well as then a few good hops are preferable to waiting for someone to bring a ladder.

EDUCATION FOR CITIZENSHIP

The education of a physician should prepare him to participate with his colleagues of the other professions and with all citizens in the "general art of the free man and citizen." Some knowledge of world history, and of attempts to solve social and economic problems, will reveal the fallacies of social schemes that have followed patterns such as that of the "Utopia" of Sir Thomas More. They were inspired by a desire to correct evident social and economic difficulties or governmental abuses but failed because they violated social principles or economic laws of supply and demand, or attempted to regiment a free economy and the lives of citizens. Similar schemes under various disguises, such as economic planning, federal class subsidies, and government by administration rather than by law, have been recently current here and call for an informed leadership so that we may avoid the dangers that still threaten us. An understanding of economics will unmask the false bases of Marxian theory and reveal the inevitable ruin inherent in socialistic and communistic programs. A managed economy is the weapon of a dictator. Even a limited knowledge of the history of nations of the world wil make an educated man more tolerant of religions other than his own and of national ideologies as dictated by tradition, climate, geography, natural resources, population, and food supply. He will recognize the destructive intent and effects of the atheism of Marx and communism and of the effort to regiment humanity and subject all men and women to a single pattern of existence. H will distinguish between "social change" required b higher standards of living and "socialism," whic threatens the economic foundations that have made these higher standards of living possible. Despite his justifiable dissatisfaction with the course of international relation particularly those of recent years, he will hesitate t impose an idealistic, but at present unworkable, system of world government on nations that do not understand it and do not want it. Such proposals have fostered tendency favored also by communistic thought to deci patriotism and love of one's own homeland and a sume to override desires and ideologies of other n tions that may have the same patriotic impulses as do ours. Patriotism, devotion to the homeland, is a secula expression of the spiritual values of tolerant religion They are complementary, and the one enhances th other.

Good qualified leaders in the community, the state or the nation are scarce. We see leaders come and go A man may possess some ability to lead his follower but lacks character, or ideals, or a knowledge of histor and economics, or discrimination between the mediocr and the best; in short he lacks what Sir Richard Livingstone terms the "philosophy of the first rate." The foundation of the philosophy of the first rate and of soun leadership, whether in medicine or in universities o in other activities of citizenship, is a sound cultural education and a continuing faith in the religions of our forefathers.

In any community there are a few leaders; the res are followers. When good leaders are not replaced by their kind, good leadership is slowed or ceases; the followers become discontented and disorganized and readily accept inferior leadership. Spiritual, social, and material retrogressions ensue. This sequence is evident in the history of nations and civilizations of the past. Signs of the same process have appeared in recent years in our own country and demand sound education to save us from pseudoliberals and from the bad leadership of a superficially informed but unintelligent intelligentsia.

CONCLUSIONS

And so we return to the primary definition of the purposes of education. The physician should have a sound vocational training in the acquirement of which a broad general university education, or its equivalent, is fundamental. By it he will learn "how to learn" as well as "what to learn." The profession of medicine is more than a technology. In addition to technical knowledge and skill the physician needs a philosophy of the first rate—character, integrity, conscientiousness, humanity, and a love for the practice of medicine. In the cure and alleviation of the physical and mental ills of mankind, the physician requires an appreciation of the psychological, environmental, social, and economic problems, as well as the physical problems, of his patients.

The triumphs of medicine have added to the stature of the physician in his community, and with this increased influence have come added responsibilities for clear thinking and leadership, for which he must be prepared. The physician shares with those in the other professions the obligations of citizenship, obligations more binding by virtue of his professional relations to the community. In the procession of advancing civilization neither science nor humanities can march alone.

122 S. Michigan Ave. (3).

TRAINING OF RESIDENTS IN RADIOISOTOPE TECHNIQUES

Donald S. Childs Jr., M.D., Rochester, Minn.

The production and availability of radioactive isotopes have presented to the medical profession many valuable agents for use in the fields of medical diagnosis, therapy, and research; however, the basic knowledge and disciplines necessary for the proper use of these substances are not familiar to the average physician. Since radioactive isotopes are potentially dangerous both to the patient and to all engaged in their preparation and administration, the problem of providing the basic knowledge, training, and experience for their safe use has been of grave concern to those charged with the responsibility of distributing the radioisotopes for medical use. Several radioisotopes are being used essentially as substitutes for x-rays and radium. Radioactive cobalt (Co^{60}) teletherapy, radioactive strontium (Sr^{90}) beta applicators, and radiogold (Au^{198}) wire are examples of these uses. The manner of use of these isotopes is similar to that of beta and gamma rays of radium and x-rays and requires very little additional knowledge for men trained in radiation therapy. Other isotopes, such as radioactive iodine (I^{131}), radioactive phosphorus (P^{32}) and radiogold (Au^{198}) colloid, which are administered internally and metabolized by the body, require new and different techniques, new ideas of dosage and dosage distribution, and the knowledge of the pharmacology, physiology, and metabolism of the particular isotope. These concepts are new and require the acquisition of new information.

I^{131}, P^{32}, and Au^{198} have already become accepted agents in medical diagnosis and therapy. Several other radioisotopes hold great promise of becoming useful routine agents in the near future. Many physicians wish to have these isotopes available for their patients. However, the dangers inherent in their use have resulted in limitation of their distribution to persons who fulfill certain criteria of training and experience. When radioactive isotopes first became available for medical use numerous specialists possessed fragmentary information and training that were valuable in the application of these radioactive sources to medical problems. Such persons included radiation physicists, biologists, physiologists, radiologists, endocrinologists, hematologists, and pathologists. The cooperative effort of such individuals resulted in the institution of radioisotope programs in many centers. The necessity for the cooperative participation of individuals in these special fields is reflected in the make-up of radioisotope committees, which are an integral part of radioisotope programs in many institutions today.

TRAINING AND EXPERIENCE FOR PRACTITIONER

How can the busy practitioner who wishes to use radioactive isotopes gain the necessary training and experience? He must learn about radioactivity and the properties of the various emissions, the theory of measuring devices, the radiological units of measurement, and the principles of radiological safety. In addition to this theoretical information, he must have practical working knowledge of the various measuring instruments, methods of assay of isotopes, methods of preparing isotopes for measurement, and information on how to practice radiological safety. Medically, he must know how to interpret the readings that his measuring instruments give him in terms of the patient and his disease, know the indications and contraindications for administering the isotopes to his patient and the biological effects to be expected from the ionizing radiation, and know how to protect himself and his technical personnel from these radiations. Ideally, this material can be obtained best by attending lectures, by reading about the theoretical aspects, by doing actual laboratory work with isotopes and the various measuring instruments, and by participating as an apprentice with another physician who is well schooled in radioisotope techniques. This preparation would require full-time schooling for a considerable length of time, which is usually impossible for the practicing physician. The courses, one month in duration, given frequently throughout the year at the Oak Ridge Institute for Nuclear Studies afford an excellent basis in the theoretical and practical aspects of the physical side of radioisotope work. The acquisition of medical expe-

Read before the meeting of the Society of Nuclear Medicine, Seattle, Wash., May 29 and 30, 1954.

rience, however, is more difficult to obtain. An ideal time for a physician to acquire the necessary training in medical radioisotope work would be in conjunction with his residency training. During this period he should be willing to spend the necessary time to receive the training and necessary fundamental knowledge and experience to serve as the basis for his later practice.

If institutions that have an active radioisotope program in operation can arrange an adequate program for residents desiring such training, a supply of physicians trained in the medical aspects of radioisotopes will become available. Several institutions have established formal programs for residency training, many others supply such training informally, and many institutions equipped to do so have not as yet set up such programs.

At the Mayo Foundation a formal training program in radioisotopes has been offered for the past 18 months to fellows in radiology. These fellows are assigned to this service full-time for a period of three months. This period seems to be fully adequate when it is considered that these radiology residents have already received much of the theoretical material in radiation physics and have obtained practical experience in the clinical effects of ionizing radiations in their work with patients receiving radium or roentgen therapy. The objectives of this training program are to present to the resident the fundamental material regarding radioactivity and the properties of radiation, to teach him how to handle radioactive materials safely, to give him practical experience with the various measuring instruments, to let him participate actively in the administration of beta and gamma ray-emitting isotopes to patients and care for these patients after administration, and to impart the philosophy regarding clinical radioisotope practice held by the staff here. For purposes of discussion the curriculum may be divided into three main categories.

THEORETICAL PRINCIPLES

The theoretical principles are presented by means of lectures, demonstrations, and reading material. The main subjects are basic mathematics, units of matter, radioactivity, physical properties of radiation, biological effects of radiation, radiological safety, theory and use of measuring instruments, radiological units—dosimetry, and tracer methodology. Most medical residents have had little background in the mathematics pertaining to radioactivity. A short, uncomplicated, practical discussion of logarithms, exponents, and necessary statistics at the outset of the period is helpful for the understanding of the material to be presented later. The slide rule is almost a necessity for isotope workers. A short demonstration of the basic manipulations for multiplication and division plus the need to use the rule in his practical work will provide the stimulus for the trainee to learn the use of this valuable aid. Discussion of the fundamental nature of matter and radioactivity at a fairly elementary level is necessary and sufficient for the needs of these men. Too complex a presentation confuses the student with too many new concepts and may result in the retention of none. The approach to the properties of radiation is coordinated with that of the biological effects of ionizing radiations and radiological safety. It is in these latter two fields that this material will be used.

Discussion of the measuring instruments is accompanied by demonstration of the instruments and their operation. The advantages and limitations of the various types of instruments are stressed. Discussion of radiological units and dosimetry includes equivalent ionization and energy absorption units; biological, effective, and physical half-life; dosimetry of beta ray emitters; and dosimetry of gamma ray emitters. Tracer methodology is largely of use in research fields outside the scope of this training. A short discussion is included to show the resident that there are pitfalls in tracer methods and certain criteria to be met in designing experiments using radioactive isotopes. In addition, knowledge of the tracer method will enable him to advise his colleagues doing research concerning precautions to be taken in the use of isotopes, the possibility of radiation effects modifying the result, and estimation of radiation dosage delivered to the experimental material.

We have found the sound motion pictures produced by the Army Signal Corps in conjunction with the isotopes division of the Atomic Energy Commission to be a useful aid in presenting much of this material. The fact density in these films is great, and to obtain the greatest benefit they must be shown more than once and in conjunction with the lectures on the subject covered. These films are available on loan from the Army or may be purchased at a reasonable rate from a commercial firm. My colleagues and I have found the following films useful: Fundamentals of Radioactivity, Properties of Radiation, Practical Procedures of Measurement, Methodology, Principles of Radiologic Safety, and Practice of Radiologic Safety.

PRACTICAL APPLICATIONS

Some of the practical procedures carried out by the residents are identification of radioisotopes, calibration and use of measuring devices, preparation of radioactive material for assay, in vivo and in vitro assay of material containing radioisotopes, autoradiographic procedures, safety procedures, survey for radiation hazards, decontamination and waste disposal, and bookkeeping. It is of utmost importance that the trainee gain as much practical experience in the various radioisotope techniques as possible. Many of the more routine procedures of counting and assay are performed in the larger centers by technical personnel. However, there is as great a shortage of these technical personnel as there is a shortage of properly trained physicians and radiation physicists. It is probable that the resident will have to supervise the training of such personnel when he institutes his own program at a later date. His effectiveness in training such personnel will be greatly enhanced if he has practical experience with such procedures himself. A considerable portion of the resident's time during the training period is devoted to such work. He performs the routine procedures in use in the laboratories aided by the technician. Other widely used or accepted procedures not part of the routine in our laboratories are performed as laboratory exercises. An attempt is made to give the resident as comprehensive a basis as possible of various assay, preparation, and counting methods and experience in their use.

Considerable emphasis is placed on the safe handling of the various radioisotopes and the methods for achieving this. The efficiency of the various methods is brought out by exposure inventories of each step in each procedure used. When new procedures are considered, the resident helps to establish safe methods by doing radiation exposure surveys of the entire procedure. Our residents in radiology are most cooperative in the matter of radiological safety. They realize that they will be receiving exposure from fluoroscopic procedures, radium, diagnostic and therapeutic x-rays, and isotopes and are anxious to keep all such exposure to a minimum. This radiation exposure awareness among the residents has provided the stimulus for improved protection facilities and practice not only in the radioisotope work but in the other branches of radiology as well. The residents' constant evaluation and criticism of the methods in use have resulted in improvements in technique and reduction in exposure of personnel throughout the institution.

Orderly and systematically kept data are invaluable in calculations, in checking back for possible errors, and in following changes in the material being studied. The value of good bookkeeping becomes apparent to the resident as he performs his technical duties. In fact, the bookkeeping in our section has been greatly improved by the criticism and suggestions of our residents in training.

CLINICAL ASPECTS

Administration to human beings of potentially dangerous substances, whether radioactive isotopes or any other form of medicament, requires assessment of the possible benefits to be achieved against the possible damage to be encountered. In the case of radioactive isotopes, some of the potential benefits and dangers are known and some are not. Knowledge of the disease, the patient, the pros and cons of other methods of treatment, as well as the isotope method, all contribute to the decision of whether such treatment should be undertaken. Medical judgment cannot be taught. The responsibility of the preceptor is to impart as clearly as possible his reasoning in coming to his decision. The trainee then begins to form his own philosophy, based at first on that of his preceptor and on his reading and later modified as his own observations and experience are acquired.

In radioactive isotope training, just as in other training of medical residents, the ideal is to provide the trainee with the basic information, guidance, and experience so that he may draw on this material in his later practice to provide sound medical care to his patients. The trainee should consider the following clinical aspects with regard to the patient: (1) medical workup, (2) indication for the use of the isotope, (3) care after administration, and (4) evaluation of results. Regarding use of the isotope, the following aspects should be considered: (1) isotopes in general use—behavior in human beings, effects on disease processes, and limitations; (2) methods of administration; (3) survey of isotope distribution in patient; and (4) assay of isotope in excreta.

In practice the resident takes the history of the patient and examines him. He discusses the features of the case with the consultant and participates with him in the plan of treatment. He assists in the preparation, assay, and administration of the isotope and follows the patient in the postadministration period. It is our practice to assign a resident to a particular patient and to have him perform all the technical as well as medical work with that patient until the patient is dismissed. If possible he will also see the patient on follow-up visits, but, since the training period is short (three months), his follow-up experience is usually limited to seeing patients on whom other residents have worked. Weekly round-table discussions are held at which the problems presented by patients currently under observation are discussed, recent publications of interest are reviewed, and a short pertinent subject is presented.

Active clinical experience at the present time is confined to three isotopes. The residents learn the use of I^{131} for diagnostic tracer tests for thyroid function and for tracer evaluation of thyroid cancer suspects including survey and autoradiography. They learn the correct types of therapy of hyperthyroid states and of carcinoma of the thyroid, as well as therapy needed to produce myxedema in patients with extrathyroidal disease—for example, angina pectoris or pulmonary emphysema. They receive training in the use of P^{32} for treatment of polycythemia vera and for treatment of chronic leukemias. They learn the use of Au^{198} colloid for treatment of pleural and peritoneal malignant lesions.

During the three month period sufficient experience is usually accumulated in most of the foregoing categories. Therapy of thyroid cancer is an exception. There are very few patients with cancer of the thyroid who are suitable for a full-scale treatment program with I^{131}. In addition, the administration of such treatment may run into a period of several years. In such a situation the records of all patients in our series are carefully reviewed with the residents to give them an idea of how such treatment is carried out and the results achieved to date. In addition to the foregoing isotopes, both clinical and research work is being done using other isotopes. The residents are made aware of such work and urged to follow its progress to be aware of the scope, usefulness, and applications of these isotopes as a research tool. Should the resident desire to carry out a research project himself, facilities are available for such work. This, of course, requires the expenditure of more time than is allotted to the radioisotope training period. In the past, I think that the residents who have performed such projects have received more benefits from the increased time expenditure than has been lost by the forced neglect of other aspects of their training.

COMMENT

Clinical use of radioactive isotopes is rapidly changing and progressing. In the design of a training program, it is impossible to anticipate many of the possible uses to which radioisotopes may be put in the future. The purpose of the program outlined is to provide the trainee with the background and experience so that he may participate intelligently in the future development of this phase of medical practice. At the present time it seems necessary for residents to devote considerable time to such a training program. This is because of the introduction of many new disciplines and concepts to which they have not been exposed previously. However, the youth of today in grade school and college have knowledge of such things as Geiger counters, gamma rays, neutrons, and the like. Medical students are taught about the use of radioisotopes as routine research tools and as medical diagnostic and therapeutic agents. The residents of the future should have a much more comprehensive idea of these subjects, and the need for spending considerable time on the fundamentals will be gone. When that time comes, the radioisotopes will take their rightful (and less glamorous) place as routine agents of the physician.

200 First St. S.W.

THE PHYSICIAN'S RESPONSIBILITY TO MEDICAL ORGANIZATIONS

Everett C. Fox, M.D., Dallas, Texas

Hippocrates, the "father of medicine," is remembered in history not only for his contributions to medicine but also for his code of ethics and lofty ideals. Historically and traditionally, the physician has been dedicated to the service of his patients and has been a respected member of the community. The duties of a physician were quite simple: He took care of his patients as best he could. But in recent years, this has been changed for our generation of physicians and probably for future generations. We still assume our principal duties of the care of the ill but have been forced out of our traditional orbits into many spheres of activity. It has become necessary for us to become better informed and to exert a wholesome and constructive influence upon the economic, social, and political affairs of our community, state, and nation.

BROADER RESPONSIBILITIES TODAY

These necessary activities take much of the time and energy that the physician might devote to his patients. The physician of today has a great responsibility to his profession and should participate actively in the functions of his county, state, and national medical associations. Today, a physician must be well informed about medical, scientific, economic, social, and political problems and should be able to discuss them intelligently and articulately. He must devote considerable time to the duties of the committees of his county and state medical associations, to his hospital staff, community agencies, service clubs, and other organizations. I do not need to mention how arduous these tasks may at times become. Effective work on medical society committees such as voluntary health insurance, emergency call service, mediation, physician placement, public relations, and veterans' affairs may determine if your patients will receive as good medical care in the future as they have in the past. These new activities are part of our duty and responsibility to our patients. If we cannot keep medicine free, the ultimate losers will be our patients. We must lend every support to our voluntary hospital system, serve willingly and diligently on staff committees, and assist in the instruction of the intern and resident staffs and the nursing personnel.

The county and state medical associations have rendered great service in the study of these problems and have furnished many satisfactory and acceptable answers to the numerous issues confronting us. But the great burden of the study of many of the scientific, economic, and political problems must be at the national level. Only a few of us have recognized the importance and effectiveness of the many activities of the American Medical Association.

FUNCTIONS OF THE AMERICAN MEDICAL ASSOCIATION

The American Medical Association, through its Board of Trustees, the House of Delegates, and its various councils and committees, has rendered a great public service to the American people by its constant alertness to the political and scientific problems presented and by its recommendation of sound, fair solutions for the welfare of the public, the advancement of scientific medicine, and the betterment of the public health. The A. M. A. represents more than 150,000 physicians from 53 states and territories and 2,000 county and district medical societies. The annual budget is over 9 million dollars, 60% of which is received from dues and subscriptions to THE JOURNAL. More than 5 million dollars is expended on scientific activities and over 2 million on public information and socioeconomic activities. The 190 members of the House of Delegates elected by the states, territories, and sections determine, activate, and supervise the policies of the A. M. A. They are the legislative body for the American physician.

Scientific Activities.—The major emphasis of the A. M. A. is upon scientific activities that are largely conducted by the Council on Scientific Assembly with its 21 sections, the Bureau of Exhibits, the Council on Medical Education and Hospitals, the Council on Mental Health, the Council on Industrial Health, and the Division of Therapy and Research, which includes the Council on Pharmacy and Chemistry, the Council on Physical Medicine and Rehabilitation, the Council on Foods and Nutrition, the several standing committees of these councils, the Committee on Cosmetics, the Bureau of Investigation, and the chemical and physical laboratories. The work of these councils is especially important in advancing the science of medicine. The outstanding reputation of the council members for specialized scientific knowledge and integrity is well recognized. They serve without remuneration and render unbiased decisions based on careful considerations of all available scientific evidence and expert opinion.

Socioeconomic Activities.—Every physician today must concern himself with the social and economic aspects of the practice of medicine as it reflects on the patient, the public, and the profession. The A. M. A. acts collectively for the individual physician in the socioeco-

---

Chairman's address, read before the Section on Dermatology and Syphilology, at the 104th Annual Meeting of the American Medical Association, Atlantic City, June 8, 1955.

nomic field, which includes ethics, laws and legislation, medical service, economic research, rural health, and health education. The activities in these fields are carried out by the Council on Medical Service and its seven special committees that deal with medical care for industrial workers, relations with lay-sponsored voluntary health plans, prepayment hospital and medical service, extension of hospitals and other facilities, indigent medical care, federal medical services, and maternal and child care. The Council on Medical Service studies the social and economic changes in the practice of medicine and reports these changes, conducts surveys, and acts as an information center for the profession and the public. The Council on National Defense, the Council on Rural Health, the Judicial Council, the Bureau of Medical Economic Research, the Bureau of Health Education, the Committee on Legislation, the Law Department, the Department of Public Relations, and the Washington Office provide information for physicians and allied health agencies.

Publications and Related Activities.—The third important activity is the scientific publications. THE JOURNAL of the American Medical Association, established in 1883, publishes 165,000 copies weekly and is the most valuable medical publication in the world today. There are also nine special A. M. A. journals, including the *A. M. A. Archives of Dermatology.* In addition, the A. M. A. publishes the Quarterly Cumulative Index Medicus, the Standard Nomenclature of Diseases and Operations, New and Nonofficial Remedies, *Today's Health,* and the American Medical Directory.

Important related activities include the Women's Auxiliary, the Student American Medical Association, and the American Medical Education Foundation. More physicians should become financially acquainted with the last organization. Someone provides approximately $10,000 above the cost of each doctor's medical education. Physicians are now asked to return at least $100 annually, individually, to help provide for the financial support of the medical schools. The above lists of councils, committees, the House of Delegates, the officers, and the Board of Trustees of the A. M. A. represent about 500 physicians. These men are doing much of the effective work, study, and evaluation necessary to determine the policies, programs, services, and accomplishments of American medicine. They are dedicated to the purpose of the promotion of the science and art of medicine and of providing better medical care for the American people. They are elected representatives from state societies and scientific sections. Many other physicians have helped in the advancement of scientific medicine by developing our many special societies, colleges, and academies and by organizing and supervising specialty boards.

VOLUNTARY HEALTH INSURANCE

As physicians, we must accept our scientific and economic obligations to medicine, to medical education, and for the improvement of the medical care of our patients. We should give assistance to the development of the voluntary health insurance plans that now protect 100 million people from the major costs of illness, a cooperative effort of hospitals, insurance underwriters, and physicians in every state of the nation. Recent surveys reported to the American Hospital Association showed that, in 1940, 60% of the population favored government compulsory health insurance, while recent polls show this figure has decreased to 19%. Doubtless the effectiveness of the voluntary health insurance plans has strongly influenced this trend. This change of opinion occurred during an era when government was spending millions on propaganda for socialization. Since 1900, during part of this same period, scientific advances have increased life expectancy 20 years. We all realize that the cost of medical care has increased during a period of inflation, development of new drugs, increased usage of medical care, and increased demands for hospitalization. However, the U. S. Bureau of Labor Statistics shows that the consumer price index was 92% higher in 1954 than in 1935-1939, but medical care costs rose only 74% and physicians' fees only 60%. Private expenditures for medical care totaled 9.9 billion dollars in 1953, a 37% increase over 1948 according to reports by the Social Security Administration. In the five year period, voluntary health insurance benefits increased by 217% to 1.9 billion dollars and met 20% of the total medical bill, compared with 8.4% in 1948. Hospital insurance benefits were 455 million dollars in 1948 and 1.28 billion dollars in 1953; benefits for physicians' services were 151 million dollars in 1948 and 632 million dollars in 1953. The physician's portion of the medical care dollar has actually decreased since 1950.

Provision by the Veterans Administration for the care of veterans with non-service-connected illnesses, who utilize 85% of all VA beds, must have a better understanding by the public, service organizations, and the profession. The veteran with service-connected disabilities should have more and better medical care and more realistic disability payments for wartime injuries. Veterans with non-service-connected disabilities should provide their own medical care when financially able, as do other citizens, and should be a community responsibility when indigent. Social security as it affects the American people and the physician requires evaluation. Social security is a system that is neither social nor secure; advocated as insurance and as actuarially sound, social security is really a system of taxation and socialization. A system that pays $48 for one dollar of an individual's tax cannot be financially sound. Social security is not insurance; its benefits are federal gratuities paid from taxes. These and many other problems face the medical profession and the American public they serve. Physicians should be familiar with these problems and the effective policies developed for their solution.

LOCAL RESPONSIBILITIES

The physician should participate actively in his county medical society's program. He should be happy to give his time and skill to indigent medical care services. The physician's responsibility and opportunity as a citizen is important to every community. Individually and collectively, physicians are responsible for adequate medical care. They should use their ability in the development of community plans for adequate medical care. They must direct more attention to the social and economic relationships of medicine to society. A physician should have a community interest in and help develop churches, schools, chambers of commerce, health councils, and service clubs. The influence of the physician in his own community is enhanced by his interest and participation in community projects. Although he is a physician, he is also a citizen with the rights, obligations, and responsibilities of a citizen, and those rights, obligations, and responsibilities should be exercised. It is a civic duty to participate in the affairs of government.

THREAT OF SOCIALIZED MEDICINE

The suggestions presented today may require much additional time and work by many physicians. This extra time will still be devoted to patients through these social and economic activities. It is for our patients, the American public, that these tasks must be accomplished. They are the ones who will suffer the greatest if their freedom in medical care is jeopardized. The physician's basic and traditional responsibility to his patient will be advanced and maintained. The attempts to socialize medical care indicate the trend of many of our governmental agencies. The medical profession was merely the first section of the economy to come under the socialist's attack. If these measures are not resisted, they will involve industry, finance, insurance, transportation, agriculture, and education, as well as medicine.

The medical profession, through its medical organizations and with the aid of an aroused and informed public, refused to accept compulsory health insurance. If the recent trends of our national government are not changed and its paternalism, bureaucratic socialism, and one-world nationalism not restrained, all of our freedoms given by the Constitution and under the Bill of Rights will disappear. We should understand the social and economic conditions confronting us. The physician should develop a wholesome and constructive influence upon the medical, social, economic, and political affairs of his community, state, and nation.

ESTROGEN GIVEN PARENTERALLY TO CONTROL EPISTAXIS AND HEMORRHAGE AFTER ADENOIDECTOMY

PRELIMINARY REPORT

Harold C. Menger, M.D., Brooklyn, N. Y.

The control of spontaneous bleeding is a problem familiar to all physicians. In rhinolaryngology epistaxis and hemorrhage following tonsillectomy and adenoidectomy are the two most common examples of this problem. The term "spontaneous hemorrhage" is used to define marked, sudden, and unexpected bleeding.[1] It does not imply that the hemorrhage is idiopathic, although the cause may not be determinable. Nor as it is used here does it refer to bleeding resulting from the rupture of a single vessel but connotes profuse oozing from the surface of the bleeding area, wherever it might be. Finding a simple, reliable solution for these common emergencies has taxed the ingenuity of the medical profession. To control spontaneous epistaxis, many schemes of therapy have been recommended, such as vitamins K and C, anterior and posterior nasal packing, penicillin, cautery, ice packs, thrombin and fibrin foam, and ligation of the external carotid artery.[2] In certain cases, one method or a combination of these treatments is successful. Other cases resist any attempted therapy and stop as enigmatically as they begin, leaving the patient in an exsanguinated condition and in rare cases even proving to be fatal. Immediately following adenoidectomy, spontaneous oozing, if recognized, usually can be controlled with packing.[3] In an occasional case this treatment is not effective; in many it is a difficult and complicated procedure; in all it is time consuming. The purpose of this article is to offer a relatively new approach to these problems. On the basis of the results in the series to date, it is felt that the use of parenterally given estrogen is the treatment of choice in spontaneous epistaxis and hemorrhage following adenoidectomy. This study was prompted by the work of Jacobson, who reported successful treatment of over 300 cases of spontaneous epistaxis with parenterally given estrogen.[4]

REPORT OF A CASE

In the study reported here the method was first tried on a 26-year-old male who presented himself in the emergency room of the hospital with the chief complaint of epistaxis of three days' duration. The bleeding had started spontaneously and resisted all attempts to control it at other hospitals and clinics. As the patient was in an obvious state of exhaustion and exsanguination, he was admitted and received a transfusion of 1,000 cc. of blood. The nose was packed anteriorly and posteriorly, and supportive therapy with vitamin K, vitamin C, Koagamin (aqueous solution of oxalic and malonic acids), penicillin, and ice packs was instituted. The profuse bleeding was stopped, but oozing continued. On the second and third hospital days it was necessary to change the anterior packing. On the fourth day after admission, because the patient was complaining bitterly about the posterior packing and there was evidence of slight ulceration of the soft palate, the packs were taken out. There was no bleeding for two hours; then the patient began to hemorrhage profusely from the nose and mouth. At this time 20 mg. of conjugated estrogens equine was administered intravenously. The bleeding stopped within one hour. Three days later a slight oozing began; again 20 mg. of estrogen was given

intravenously. In a half hour the bleeding stopped. Within a few days the patient was discharged from the hospital; there has been no more bleeding. Because of the blood picture the possibility of the patient's having an early leukemia was considered, but this diagnosis could not be substantiated. The etiology of the spontaneous epistaxis has not been determined.

EPISTAXIS

Nose bleeds may be primary or secondary, may be induced or spontaneous, or may or may not be pathognomonic. In the majority of patients they will stop spontaneously. This fact must be considered not only in treating patients but also in evaluating any type of therapy. In some cases a small ruptured vessel can be found; these cases are usually minor and are easily controlled. However, in the more serious cases, and in all cases of spontaneous hemorrhage, there is profuse bleeding from many vessels in the nasal mucosa. Like streams swelled by a sudden rainstorm, the vessels of the mucosa seem to overflow. As the bleeding stops, there is a recession and the vascular system of the nasal mucosa reverts to its normal condition with no evidence of the previous disturbance. The primary etiology of these hemorrhages is usually difficult to diagnose, and when a patient presents himself in such a condition the primary problem is to control the bleeding. Once this is accomplished, every effort should be made to determine the cause.

TABLE 1.—*Case Histories of Six Patients with Epistaxis*

Case No.	Age, Yr.	Sex	Duration of Bleeding, Hr.	Pertinent History	Possible Cause	Treatment	Time Lapse Between Estrogen Therapy and Control, Min.	Follow-Up, Time with No Recurrence
1	26	M	72	Admitted to hospital	None known	4,000 cc. blood; 3,000 cc. glucose; coagulants; anterior and posterior nasal packing; Premarin * intravenously	60	3 mo.
2	55	M	4	Treated in office	None known	Premarin intravenously	30	4 wk.
3	47	M	3	Blood pressure 195/100 mm. Hg; treated in office	Hypertension	Premarin intravenously	20	3 wk.
4	74	F	12	Treated in office	None known	Oxidized cellulose (Oxycel) packing; Premarin intravenously	30	4 wk.
5	30	M	..	Submucous resection 2 days prior	Removal of petroleum jelly gauze packing	Premarin intravenously	30	3 wk.
6	57	M	4	Blood pressure 190/110 mm. Hg; admitted to hospital	Hypertension	Anterior and posterior nasal packing; Premarin intravenously	180	3 wk.

* Premarin is a conjugated estrogenic substance.

Since the initial case, five more have been treated and controlled with intravenously given estrogen. Although in none of them was the bleeding as prolonged and as profuse as in the original case, the epistaxis in each gave the clinical impression that it would be very difficult to control with the usual therapy. Any case of epistaxis in which no bleeding point can be found, in which the bleeding is coming from the nasopharyngeal area, or in which the bleeding has been continuous for several hours demands active attention and therapy. Each of the cases in this study fills these criteria. The therapy was 20 mg. of intravenously administered estrogen. Table 1 summarizes the data. In cases 3 and 6, the epistaxis was associated with hypertension. In case 5 profuse bleeding was provoked by removing the petroleum jelly gauze packing, which had been inserted after the submucous resection. Four patients were treated in the office, one was admitted to the hospital because of exsanguination, and the other was hospitalized because of a history of hypertension with hemorrhage. All six cases have been closely followed, and in no case has there been a recurrence of bleeding.

HEMORRHAGE FOLLOWING ADENOIDECTOMY

Because of the similarity of the bleeding in epistaxis and the profuse oozing from the operative site that occurs in some patients after adenoidectomy, it was decided to evaluate the parenteral route of administration of estrogen in these cases. This type of bleeding at times may be difficult to control, and deaths have been reported from it. The advisability of classifying hemorrhage after a surgical procedure as spontaneous may be questioned; however, it is felt justified in this instance because the two most important factors contributing to bleeding after adenoidectomy were eliminated. First, the operation was done under direct vision with a palate retractor, and all visible adenoid tissue was removed; second, the patient was kept under anesthesia as short a while as possible. Open-drop administration of ether was used because as quick a recovery as feasible was desirable to remove the likelihood of occult bleeding that might not be discovered until the patient was in a critical condition. With the elimination of these two important factors, residual adenoid tissue and prolonged recovery, any bleeding was attributed to diffuse oozing from the vessels in the palatine mucosa.

The series reported on in table 2 contains 10 cases of young children who within six hours after completion of the operation developed significant bleeding from the operative site. A small amount of bleeding is not unusual after adenoidectomy. These patients, however, were bleeding profusely. The bleeding and coagulation times in all patients were within normal limits. Because of technical considerations it was decided to give the estrogen in these cases intramuscularly. Depending on the weight of the child, either 5 or 10 mg. was the selected dose, which was given deep into the gluteal muscle. Table 2 summarizes the case histories. Each patient was checked every 10 to 15 minutes after the administration of the estrogen to determine when the bleeding had stopped. With the exception of one case that was not completely controlled until two hours after *therapy, the bleeding stopped within one hour.* The uniformity of the results and the quick response rule out the possibility of coincidence and definitely demonstrate the value of parenterally administered estrogen.

COMMENT

Why the parenteral administration of estrogen stops spontaneous hemorrhage in cases of epistaxis and bleeding following adenoidectomy is not known. At the present time it is empirical therapy. Estrogen in the management of cases of spontaneous hemorrhage was first used in the treatment of functional uterine bleeding. The female hormone appears to support the vascular integrity of the blood vessels of the endometrium. When the blood level of estrogen is markedly decreased, these blood vessels tend to rupture and bleed. The administration of estrogen stops the bleeding, probably through a reversal of this phenomenon. Estrogen may have a similar effect on other blood vessels in the body and in this manner control bleeding from other sites. A second explanation may be a beneficial effect of estrogen on the clotting mechanism of the body. Working through an enzyme system, it may either speed up the clotting process or provide some missing factor. Parenterally given estrogen has been shown to lower abnormal bleeding times in newborn infants.[5] A third explanation is the possibility that estrogen stimulates the release of thrombocytes into the blood stream. This was suggested by the blood picture of the initial case in this series. On the day before estrogen was given parenterally, the thrombocyte count was 180,000 per cubic millimeter; on the day after, the thrombocyte count was 340,000 per cubic millimeter. The possibility that this increase in platelets was produced by the blood transfusion given in the interim between the two counts was considered. But when the red blood cell counts on these two days were compared, it was noted that on the day prior to the therapy the red blood cell count was 3,150,000 per cubic millimeter; on the day after, 3,250,000 per cubic millimeter. There was, then, obviously a relative increase in the thrombocyte count. The possibility of such a property of estrogen should be considered; however, this finding in just one case is only suggestive and in no way offers proof.

TABLE 2.—*Hemorrhage Following Adenoidectomy*

Case No.	Age, Yr.	Sex	Post-operative Time of Onset, Hr.	Dose of Parenterally Given Estrogen, Mg.	Time Lapse Between Therapy and Cessation of Bleeding, Hr.
7	3	M	3	5	¾
8	6	F	4	10	1
9	5	M	5	10	½

13	6	M	3	10	1
14	5	F	2	10	1
15	4	M	6	5	1
16	6	M	¾	10	2

The significance of determining a simple reliable method of controlling spontaneous bleeding in epistaxis and hemorrhage following adenoidectomy is obvious. These two emergencies are important contributors to the rates of morbidity, and even mortality, in otorhinolaryngology. Furthermore, the strong possibility that the parenteral administration of estrogen may prove to be an important factor in control of other sites of spontaneous hemorrhage must be entertained. Value of parenterally given estrogen in managing cases due to one determinable bleeding point is not within the scope of this study. A comparison of the cases of epistaxis, in which the estrogen was given intravenously, and the cases of hemorrhage following adenoidectomy, in which estrogen was given intramuscularly, shows that the time interval was relatively the same. In no case were there any side-effects from the therapy. The results of the study were extremely gratifying. In no instance was their failure. Furthermore, the *uniformity of the response* rules out the possibility of coincidence and offers important evidence that parenterally given estrogen in some manner controls spontaneous bleeding. The evidence offered by this series of cases is too small to be considered conclusive. However, the fact that the parenteral administration of estrogen effectively controlled 6 cases of profuse epistaxis and 10 cases of severe, spontaneous hemorrhage after adenoidectomy is of extreme importance. It is hoped that future work with larger series of cases and more varied problems will substantiate the results of this series.

SUMMARY

Sixteen cases of spontaneous epistaxis and hemorrhage following adenoidectomy were treated with parenterally administered estrogen. The response in all cases was dramatic, and in only three cases was the length of time between the administration of the medicament and the cessation of bleeding over one hour. The consistency and rapidity of response rule out the possibility of automatic cessation and coincidence. Three possible mechanisms of action of estrogen are considered, but besides the passing evidence that estrogen may stimulate the release of thrombocytes, this study does not contribute any information toward the solution of the enigma. Even though the therapy at the present must be considered empirical, the effectiveness of parenterally given estrogen and the control of spontaneous epistaxis and bleeding following adenoidectomy offer strong evidence that merits serious consideration. It is hoped that future studies will not only confirm this series but also demonstrate the value of this therapy for other types of spontaneous hemorrhages.

LUMBAR TRACTION THERAPY—ELIMINATION OF PHYSICAL FACTORS THAT PREVENT LUMBAR STRETCH

Bernard D. Judovich, M.D., Philadelphia

Traction is a widely employed procedure in low back and/or sciatic pain, particularly in the conservative treatment of herniated intervertebral disks. The method usually consists of weight applied to a pelvic belt or to the lower extremities, with an average of 10 to 15 lb. on each side, usually a maximum total of 30 lb. This weight is completely neutralized or dissipated as a stretch force because of surface traction resistance of the lower body segments. These findings negate the concept that this method of traction therapy is of any value as a lumbar stretch force or that it is of any value as a stretch force in "overcoming muscle spasm" of the lumbar spine. Its chief virtue, apparently, is to confine the patient to bed. In a recent report,[1] physical evidence was presented to demonstrate that, when hanging weight traction is applied to the lower body segment, pull or stretch force does not reach the lumbar spine and its surrounding tissues and that this method is of no value as a longitudinal stretch force to the lumbar spine. This report deals with the physical aspects of lumbar traction, and no attempt is made to evaluate the effect of such therapy.

ASCENDING FORCE DISSIPATION

When traction is applied to the lower extremities, the weight required to apply stretch will vary according to the level at which stretch force is desired. The higher the segment in which stretch force is desired, the more weight will be necessary. Traction loses its effect as upper levels of body segments are reached. For example, 5 lb. would cause a stretch in the ankle but little in the knee and 10 lb. of traction would cause a stretch at the knee but little at the hip. Fifteen pounds may provide some stretch at the hip joint but none in the lumbar spine. This progressive requirement of increased traction force as upper segments are reached is due to surface traction resistance of the combined lower segments. Important factors that create and modify surface traction resistance are: (1) the area of surface contact of the body or body segments; (2) the weight of the body or body segments; and (3) the quality, contour, and texture of the contacting surfaces. In lumbar traction, surface traction resistance may be defined as the horizontal dragging force necessary to overcome these combined factors. All applied weight that does not exceed the surface traction resistance of segments below the lumbar spine is without lumbar stretch effect. After these resistance factors are overcome, only adequate additional weight will have a stretch effect upon the lumbar spine.

STUDIES AND OBSERVATIONS

In order to determine the surface traction resistance of the body and its segments, a cadaver and three live subjects were studied. The details of this study have been previously described.[1] Under uniform conditions weight was applied until it exceeded the surface traction resistance of the body, the excess weight being recorded upon a scale and head-halter attached to the head of the bed. The cadaver was then sectioned transversely through L3–L4 interspace. Leg and pelvic traction was again applied and recorded. Both hip joints were disarticulated, and surface resistance of the lower extremities and pelvis were measured. The knee joints were disarticulated, and traction resistance of the lower segments were measured. In the cervical spine it can readily be observed that no stretch will take place with 5 lb. of hanging weight. Actual figure was 6 lb. of dissipated force.

The forces necessary to overcome surface traction resistance, under the conditions described, whether it be the whole body, cadaver or living subject, or body segments, are approximately the same—they average 54% of the weight. Tone and elasticity of tissues appear to have no practical bearing upon the required force. The lower body segment (L3–L4 interspace) composes almost half (49%) of the entire body weight. Since the lower body segment is almost half the body weight and requires 54% of its weight to overcome its own resistance, 26% of the entire body weight is calculated as an approximate average figure for the force necessary to overcome the lower segment resistance. The 26% of the total body weight that is required to overcome the surface resistance of the lower body segment is designated as the dissipated force factor. This force is completely neutralized and lost as a stretch force to the lumbar spine. The only traction force that could have any lumbar stretch effect is that which exceeds the amount needed to overcome the surface traction resistance of this segment. The force required with pelvic traction is the same as that with Buck's extension. In one instance the lower body segment is being pushed and in the other being pulled to the foot of the bed. The Trendelenburg position with a 6-in. elevation of the foot of the bed yielded only a 5% increase in countertraction. This increase in countertraction produced by the Trendelenburg position is not worthwhile in view of the resultant dependent headache and the anxiety produced by unnatural position for prolonged periods. When sufficient weight is applied to cause the body to shift slightly toward the foot of the bed, an illusion of end-point weight is created. This is due, however, to the shearing deformity of the mattress. With a resilient sponge rubber mattress, this will occur with much less weight.

From the Pain Section, Department of Neurology, Graduate School of Medicine, University of Pennsylvania.

Dr. L. Richard Schumacher assisted in this study.

[1] Judovich, B. D.: Lumbar Traction Therapy and Dissipated Force Factors, Journal-Lancet **74**: 411-414 (Oct.) 1954.

[2] Judovich, B. D.: Herniated Cervical Disc: New Form of Traction Therapy, Am. J. Surg. **84**: 646-656 (Dec.) 1952. Judovich, B. D., and Bates, W.: Pain Syndromes: Diagnosis and Treatment, ed. 4, Philadelphia, *F. A. Davis Company*, 1953. *Shenkin, H. A.: Motorized* Intermittent Traction for Treatment of Herniated Cervical Disk, J. A. M. A. **156**: 1067-1070 (Nov. 13) 1954.

The therapeutic results of lumbar traction have not been nearly as dramatic and satisfactory as those often obtained with heavy cervical traction.[2] This can be partially explained by the lighter structures of the cervical spine, the satisfactory countertraction of the body weight, and the smaller loss due to surface traction resistance. In the past, it had been my practice to administer an average of 60 to 80 lb. of pelvic traction, using a motorized intermittent traction apparatus. Present findings reveal that in the average patient, the first 40 to 45 lb. were being lost as a lumbar stretch force, so that actually only 20 to 40 lb. of traction were obtained. This amount, although sufficient for the cervical spine, would appear to be inadequate for the lumbar spine with its comparatively dense structures.

ELIMINATING RESISTANCE OF THE LOWER BODY SEGMENT

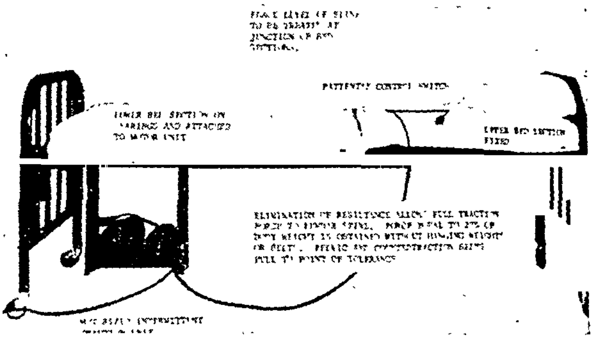
Lower body segment resistance can be totally eliminated in the following manner. A bed is built in two sections: the upper is fixed and the lower is mobile upon roller bearings and is transported by a motorized intermittent traction unit (see figure). Each section has its mattress. With the sections closed, the patient is placed supine upon the bed, with the lower spine at the junction of the sections. The resistance of the lower body is no longer a factor since it is transported mechanically. The force exerted at the lower spine is equivalent to the countertraction value of the upper body segment. This is approximately 27 to 28% of the total body weight (54% of 49% of total body weight). This entire force is exerted at the bed split and is obtained merely by lying upon the bed without weight or belts. Should greater traction force be desired a pelvic belt is attached to the lower edge of the moving section, and a countertraction belt is attached to the upper bedposts. In this manner unlimited traction force can be obtained. Hanging weight traction without the use of a motorized mechanism can be obtained with only a loss of 2 or 3 lb.

Body and Body Segment Weights

Segment	Weight Lb.	(Kg.)	%
Whole body	118	(53.5)	100
Lower body segment (L3-L4)	58	(26.3)	49.2
Pelvis	25	(11.3)	21.2
Lower extremities (hip disarticulation)	16.5	(7.5)	13.9
Thigh	10	(4.5)	8.5
Leg and foot (knee disarticulation)	6.5	(2.9)	5.5
Head and neck (C6-C7)	10	(4.5)	8.5

SUMMARY

Live subject and cadaver studies reveal that the average surface traction resistance of the body in a hospital bed is approximately 54% of the total body weight. The lower body segment (transverse section through L3–L4 interspace) weighs approximately 49% of the total body weight. It also requires approximately 54% of the weight of the lower body segment to overcome its own surface traction resistance. This is equal to approximately 26% of the total body weight. The force, therefore, that is dissipated with leg or pelvic traction is approximately 26% of the entire body weight. Only adequate weight in excess of this amount has a stretch effect upon the lumbar spine. There is progressively increased force dissipation ascending to higher body segments. Present methods of constant weight traction therapy to the lumbar spine are by far inadequate and produce no stretch effect upon the lumbar spine or its surrounding tissue. This is due to the fact that insufficient pull is applied to overcome the surface traction resistance of the lower body segment. The concept that hanging weight traction to the legs or pelvis provides stretch, or that it overcomes lumbar muscle spasm by such stretch, is, in view of the physical findings presented, without foundation. A method I have devised for overcoming surface traction resistance of body segments allows minimal weight to produce stretch at desired body levels. No attempt has been made at this time to evaluate the effect of traction therapy upon the lumbar spine.



PLACE LEVEL OF SPINE TO BE TREATED AT JUNCTION OF BED SECTIONS.
LOWER BED SECTION ON BEARINGS AND ATTACHED TO MOTOR UNIT
PATIENT'S CONTROL SWITCH

Gangrene Following Intravenous Therapy.—Apparently neonatal spontaneous gangrene is especially referable to long and difficult labor. All cases of infant gangrene appear to be associated with infection. . . . Particular care should be given to those infants with severe general sepsis, cachexia, and poor tissue nutrition. Lowered resistance in infections is undoubtedly one cause of poor vasomotor response in infants and contributes to ultimate local tissue death even when the outcome is not fatal to the child. Every aseptic safeguard should be exerted against inviting local infection by careless procedure and thus overburdening the already critically ill infant. Careful handling of tissues for venipuncture is necessary, and especially for incision over a vein, which is imperative not only to prevent infection but to prevent accidental severance of an artery. The vessels should be exposed meticulously, with gentle introduction of the needle or polyethylene tube. . . . Before intravenous therapy is instituted for the sick infant, one should weigh the status of the cardiovascular system and proceed cautiously in the face of any observable signs or deducible implications of circulatory disturbance or inadequacy; for example, the age of the child is indicative, for the younger the sick infant the greater the hazards of emboli or thrombosis. Vasomotor instability of the tissues invites infection, gangrene, and death of tissues or even of the child. Both dehydration and overhydration are dangerous. Of the two . . . overhydration is the greater danger.—D. S. Miller, M.D., Ph.D., and R. Sebeck, M.D., Gangrene of the Extremities in Infants Subsequent to Intravenous Therapy, *A. M. A. American Journal of Diseases of Children,* August, 1955.

TWENTY-FOUR HOUR MEDICAL ANESTHESIA COVERAGE FOR OBSTETRIC PATIENTS

John J. Bonica, M.D.
and
George H. Mix, M.D., Tacoma, Wash.

During the past two decades there has been a greater appreciation of the importance of good obstetric anesthesia by most physicians who care for parturient women.[1] It is now fully realized that if maternal and fetal mortality and morbidity are to be reduced further, it is essential that women in labor receive the best service that modern anesthesiology is capable of supplying.[1c] Certainly there is no justification for the misconception that obstetric anesthesia is a relatively simple procedure that requires less skill than the administration of surgical anesthesia. On the other hand, there is a great deal of evidence to indicate that the administration of anesthesia for obstetric procedures is often more complex and requires more skill than do many surgical operations.[2] In addition to the fact that two lives are involved instead of one, it is necessary to consider that special mechanical and physiological problems of pregnancy reduce the flexibility and margin of safety in the choice and use of certain methods of anesthesia. Moreover, women in labor frequently cannot be prepared properly and consequently present the additional hazard of aspiration of gastrointestinal contents. Medical complications such as the toxemias, as well as the irregular fashion in which these patients receive medication, constitute additional problems that often tax the efficiency of the obstetric team and that justify the thesis that obstetric anesthesia deserves the interest of the expert anesthesiologist.

Unfortunately, all too frequently this phase of medical practice is relegated to someone who is relatively inexperienced or who has only a casual interest in this field. It has long been the custom to assign the least experienced anesthetist and the oldest anesthetic apparatus to the delivery room. In some instances, interns and residents in obstetrics and even an obstetric nurse without any training in anesthesiology are requested to administer the anesthetic. Investigation reveals that in many institutions obstetric anesthesia remains an unwanted and, therefore, a neglected portion of the broad fields of anesthesiology.[3] Some of the best hospitals in this country provide their parturients with a quality of anesthetic service that would never be tolerated in their operating rooms.

There are several reasons for this state of affairs, not the least important of which is the fact that until recently there has been a general scarcity of trained anesthesiologists. Moreover, the lack of interest demonstrated by some teachers has caused many anesthesiologists to finish their training with a passive attitude and with a notable lack of interest toward this phase of anesthesiology. Some anesthesiologists in private practice, while admitting the importance of obstetric anesthesia, avoid as much as they can this important responsibility. They justify this attitude by pointing out that because of its emergency and unpredictable nature obstetric anesthesia encroaches unduly upon the time of the anesthesiologist and interferes with his surgical anesthesia practice. It is argued that it is physically unfeasible to give complete anesthesia coverage to the obstetric department and still run an active surgical schedule. A further pertinent reason given for the depreciation of the importance of obstetric anesthesia is that the financial remunerations frequently are not commensurate with the services rendered.

It is the purpose of this paper to demonstrate that it is feasible in every respect to provide a 24-hour medical anesthesia service to obstetric patients by describing the organization, development, and functioning of a particular group that practices in a 215-bed private hospital wherein approximately 2,500 deliveries are performed each year. In discussing the organization and development of this phase of our practice, mention will be made of the factors that are important in making such services not only feasible but also practical and that work to the best advantage of all concerned.

PLAN OF ORGANIZATION AND FUNCTION

In order to provide a proper perspective of this subject, it is necessary to describe briefly the plan of organization and function of a group of anesthesiologists that provides service not only to the hospital under discussion but to several other institutions in Tacoma. This group had its inception in January, 1952, when one of us (J. J. B.) resigned as a hospital-employed anesthesiologist and entered private practice. During the ensuing four years there has been an evolutionary growth of the group. For several months after its inception we continued to rely on nurse anesthetists to provide the majority of the obstetric anesthesia. As the demand for medical anesthesiologists became progressively greater, technicians were replaced by physicians who had completed their training or were in the process of doing so. This trend was promoted and encouraged because it was believed that in order to discharge properly all of the duties and obligations associated with the anesthetic management of obstetric patients, it is necessary to have

the background of a physician. It is for this reason that in recent years it was preferred to use residents to help during the transition period. At the present time the group consists of seven anesthesiologists, of whom three are diplomates of the American Board of Anesthesiologists and the rest have finished the required training. In addition, there are eight residents in various states of training and three interns who are on the anesthesiology service for a minimum of six weeks. Of this group four attending anesthesiologists and four to five residents are assigned to Tacoma General Hospital, where they provide all of the anesthesia service. This hospital cares only for private patients and has five operating and three delivery rooms. In 1954, 3,379 surgical operations and 2,359 deliveries were performed.

On a typical day three or four of the attending anesthesiologists and four of the residents will be on duty until the elective surgical schedule is completed. Since usually only four of the five operating rooms are used at any one time, there are usually three anesthesiologists available for obstetric service, even at the height of the surgical schedule. Although it varies with the types of surgical operations, in most instances at least two of those attending are available to administer obstetric anesthesia. These people may be located in the surgical pavilion if they are needed to supervise the resident, but if there is any activity in the obstetric pavilion they are usually found there. In any case, the operating rooms are in such close proximity to the obstetric pavilion that an anesthesiologist is available within a matter of seconds for consultation or to administer an urgent obstetric anesthetic.

After the elective surgical schedule is completed, at least three anesthesiologists are available for obstetrics and emergency surgery. In actuality an even greater number of anesthesiologists are available for the greater part of the day because after the schedule is completed, postoperative and postpartum rounds, the teaching program, and other administrative duties keep most of the personnel in the hospital. The three individuals on call usually consist of one attending anesthesiologist, one second year resident, and one first year resident. The attending anesthesiologist remains in the hospital until late in the evening and either administers the anesthetics himself or supervises the resident, depending on the particular circumstances. In this way, the residents receive personal instruction and direct supervision not only in inhalation and saddle block anesthesia but also in various types of highly technical procedures such as single or continuous segmental peridural and caudal blocks. Moreover, an effort is made to inculcate the importance of obstetric anesthesia and to imbue the residents with the enthusiasm that is necessary to accept this phase of practice. If there is no activity in the labor room, the attending anesthesiologist then goes home but remains on consultation call for all cases. During the night the anesthesiologist on first call sleeps in one of the rooms on the obstetric floor so that he or she is available within two or three minutes. The anesthesiologist on second call also remains in the hospital.

If more than three anesthesiologists are needed for emergency obstetrics and surgery, the person on first and second call in one of the other hospitals can be summoned to help. This is rarely the case because the amount of emergency surgery in this hospital is relatively small. This call schedule may be considered rigorous by some because each anesthesiologist is on call approximately every third night, but we do not find it difficult since the person on first call is off the next morning; the person on second call may be called once or twice during the night, while the person on third call is not usually called after midnight except for consultation or in the event of complications.

Whenever possible, the obstetric patients are seen before the administration of anesthesia because this affords the anesthesiologist the opportunity to obtain a history, particularly regarding previous anesthesia, and to discuss the type of anesthesia that is to be used, and, what is even more important, to give him an excellent opportunity to develop rapport. The patient is individualized for the choice of the anesthetic, and the decision is made after consultation with the obstetrician. We do not try to "sell" patients on any particular type of anesthesia unless circumstances warrant the use of a specific method. Although we favor regional anesthesia, we realize that many patients psychologically are not candidates for it. Since the members of the group are capable of administering all types of anesthesia equally well, we are able to offer a wide choice of methods. The decision as to the optimum time of initiating analgesia is usually made by the obstetrician, although in many instances it is left to the anesthesiologist, especially when a continuous block is to be used. All patients with regional blocks are attended by a member of the anesthesia department. Frequently one anesthesiologist attends several patients in the lying-in room who are receiving continuous blocks, but during the delivery each patient is attended by an anesthesiologist.

In addition to the administration of analgesia and anesthesia, the anesthesiologist supervises the administration of restorative fluids and drug therapy as indicated by the changing medical status of the mother. Moreover, he assumes the care of the newborn infant so that the airway is cleared immediately, the stomach is aspirated, and good oxygenation is secured promptly and continued until the infant breathes spontaneously. During the postpartum period daily rounds are made and the anesthesiologist takes an active part in the prevention and treatment of postanesthetic complications and in the management of respiratory problems in the infant. We deem it especially important to see these patients daily until they leave the hospital because this is not only proper anesthesiologic practice but also good public relations.

PUBLIC RELATIONS PROGRAM

In order to improve further our relations with obstetric and surgical patients, we have embarked on a long-range public relations program that requires the constant and unrelenting efforts of every member of the group, the obstetrician or surgeon, the nursing staff, and the hospital administration. The obstetricians have cooperated by informing patients about the department and emphasizing the advantages of medical anesthesia. The hospital administration also mails a booklet of information concerning the department of anesthesia along with other literature that is intended to inform the prospective patient about the hospital. Great emphasis is laid to proper deportment of the anesthesiologist during the postpartum visit to make the patient realize that he is a member of the obstetric team. It is a strict rule among our group that attending anesthesiologists avoid visiting patients in hospital garb but must wear street clothes, lest the patient mentally will categorize the anesthesiologist as one of the house staff. Moreover, every postpartum patient is seen by the director of the department of anesthesiology or one of the attending anesthesiologists. In addition to improving public relations, it affords us an excellent opportunity to obtain a perspective of our efforts.

Another important facet of our public relation program involves the frequent orientation of the nursing staff and the nonprofessional hospital staff, particularly those who work in the front office. With the cooperation of the director of nursing, we have been able to indoctrinate the student and graduate nurses with the importance of medical anesthesia. Our efforts in this regard are reflected by the excellent cooperation we obtain in the obstetric pavilion and on the wards. The nursing staff manifests a similar attitude and respect toward the members of our department as they do toward the obstetricians and thus imbues the patient similarly.

With this program we have encountered very little difficulty in making the patients reealize that they have received a specialized service. Moreover, this has facilitated the transition from hospital practice to private practice of anesthesiology. Patients are billed directly on a fee-for-service basis by our office, which is in a medical center located away from the hospital. All patients are sent a bill except those who have insurance with two local medical groups. We charge a basic fee for the administration of anesthesia for the second and third stage of labor. This fee, which is based primarily upon the fact that a professional service has been rendered, was decided upon by determining the duration of the average obstetric anesthesia in the hospital and what it would have cost the patient in former years when the anesthesia was administered by technicians. If prolonged blocks are administered during the first stage of labor, the fee is increased slightly for each additional hour, with a ceiling charge equivalent to four hours of anesthesia. In addition, the patient is charged a very nominal fee by the hospital for the use of drugs and equipment. At the present time it costs the patients an average of $5 more than it did for technician anesthesia. We feel that this augmentation in the over-all obstetric anesthesia fee, which represents an increase of less than 2% of the total bill in the delivery, is insignificant in view of the better services rendered and must be considered as inexpensive insurance for the added safety to mother and infant. This fact is further emphasized when it is realized that the majority of the obstetric patients pay less for their anesthesia than a patient who receives anesthesia for an appendectomy.

The fee is the same whether the attending anesthesiologist or resident gives the anesthetic. This was done in order to standardize our fees as much as possible. To obviate criticism that might be made because the patients who receive an anesthetic administered by the resident alone are billed by the group, several facts may be mentioned. Firstly, the attending anesthesiologist is available for consultation call at all times. Secondly, all expenses incurred with the residency training program, including the resident's stipend, room and board, books, and expenses involved in attending meetings and obtaining guest lecturers, are paid by the group.

COMMENT

It is generally conceded that the contribution made by the rapidly developing science of anesthesiology constitutes one of the most important factors that has made possible the great advances in surgery during the past quarter of a century. Unfortunately, the same cannot be said in regard to obstetrics. While it should be readily admitted that many of the improvements in anesthetic practice have been applied to obstetrics, the contributions in this field have not been commensurate with the progress made in anesthesiology. This is especially true in regard to the administrator, a factor that, in the final analysis, is the most important to be considered. Most of the interest in obstetric anesthesia has been focused on refinement in techniques and producing better agents, but relatively little has been written or done to encourage the development of expert administrators. It serves little purpose to discuss the selection of methods of anesthesia unless there is a corresponding effort to encourage the application of these methods with the best judgment and greatest skill. A further reduction in the mortality and morbidity in obstetric anesthesia will depend to an increasing extent on the ability of the anesthesiologist and his active participation on the obstetric team to the same extent as he participates on the surgical team.[1f] Both the anesthesiologist and obstetrician must share the blame for the fact that this is not the case at the present time.

The obstetrician has been at fault for accepting, in many instances, the barest minimum of anesthetic service at the hands of the most uninformed and the least useful person in the delivery room, whereas in his gynecologic practice he would be satisfied only with the services of an expert anesthesiologist.[1e] The obstetrician should encourage and even demand that the department of anesthesiology be organized to give the obstetric service expert administration of any type of analgesia or anesthesia, any time it is desired. If anesthesiologists cannot offer such techniques as caudal, peridural, or subarachnoid blocks as a regular service, it is inevitable that they will be unavailable when most needed. The obstetrician deserves the benefit of the anesthesiologist's skill in the management of patients whose lives are threatened by hemorrhage, toxemia, or other complications, as well as in those abnormal conditions that might interfere with the lifeline of the fetus, such as prolapsed cord, prolonged labor, eclampsia, dystocia, and premature separation of the placenta. Moreover, he should derive the benefit of the anesthesiologist's skill in the management of asphyxia neonatorum and expert knowledge of depressant drugs and be able to rely on the latter to observe and evaluate the many and varied regimens of sedatives, narcotics, and amnestic drugs recommended for the first stage of labor. The obstetrician should have the interested and informed cooperation of the anesthesithe background of a physician. It is for this reason that in recent years it was preferred to use residents to help during the transition period. At the present time the group consists of seven anesthesiologists, of whom three are diplomates of the American Board of Anesthesiologists and the rest have finished the required training. In addition, there are eight residents in various states of training and three interns who are on the anesthesiology service for a minimum of six weeks. Of this group four attending anesthesiologists and four to five residents are assigned to Tacoma General Hospital, where they provide all of the anesthesia service. This hospital cares only for private patients and has five operating and three delivery rooms. In 1954, 3,379 surgical operations and 2,359 deliveries were performed.

On a typical day three or four of the attending anesthesiologists and four of the residents will be on duty until the elective surgical schedule is completed. Since usually only four of the five operating rooms are used at any one time, there are usually three anesthesiologists available for obstetric service, even at the height of the surgical schedule. Although it varies with the types of surgical operations, in most instances at least two of those attending are available to administer obstetric anesthesia. These people may be located in the surgical pavilion if they are needed to supervise the resident, but if there is any activity in the obstetric pavilion they are usually found there. In any case, the operating rooms are in such close proximity to the obstetric pavilion that an anesthesiologist is available within a matter of seconds for consultation or to administer an urgent obstetric anesthetic.

After the elective surgical schedule is completed, at least three anesthesiologists are available for obstetrics and emergency surgery. In actuality an even greater number of anesthesiologists are available for the greater part of the day because after the schedule is completed, postoperative and postpartum rounds, the teaching program, and other administrative duties keep most of the personnel in the hospital. The three individuals on call usually consist of one attending anesthesiologist, one second year resident, and one first year resident. The attending anesthesiologist remains in the hospital until late in the evening and either administers the anesthetics himself or supervises the resident, depending on the particular circumstances. In this way, the residents receive personal instruction and direct supervision not only in inhalation and saddle block anesthesia but also in various types of highly technical procedures such as single or continuous segmental peridural and caudal blocks. Moreover, an effort is made to inculcate the importance of obstetric anesthesia and to imbue the residents with the enthusiasm that is necessary to accept this phase of practice. If there is no activity in the labor room, the attending anesthesiologist then goes home but remains on consultation call for all cases. During the night the anesthesiologist on first call sleeps in one of the rooms on the obstetric floor so that he or she is available within two or three minutes. The anesthesiologist on second call also remains in the hospital.

If more than three anesthesiologists are needed for emergency obstetrics and surgery, the person on first and second call in one of the other hospitals can be summoned to help. This is rarely the case because the amount of emergency surgery in this hospital is relatively small. This call schedule may be considered rigorous by some because each anesthesiologist is on call approximately every third night, but we do not find it difficult since the person on first call is off the next morning; the person on second call may be called once or twice during the night, while the person on third call is not usually called after midnight except for consultation or in the event of complications.

Whenever possible, the obstetric patients are seen before the administration of anesthesia because this affords the anesthesiologist the opportunity to obtain a history, particularly regarding previous anesthesia, and to discuss the type of anesthesia that is to be used, and, what is even more important, to give him an excellent opportunity to develop rapport. The patient is individualized for the choice of the anesthetic, and the decision is made after consultation with the obstetrician. We do not try to "sell" patients on any particular type of anesthesia unless circumstances warrant the use of a specific method. Although we favor regional anesthesia, we realize that many patients psychologically are not candidates for it. Since the members of the group are capable of administering all types of anesthesia equally well, we are able to offer a wide choice of methods. The decision as to the optimum time of initiating analgesia is usually made by the obstetrician, although in many instances it is left to the anesthesiologist, especially when a continuous block is to be used. All patients with regional blocks are attended by a member of the anesthesia department. Frequently one anesthesiologist attends several patients in the lying-in room who are receiving continuous blocks, but during the delivery each patient is attended by an anesthesiologist.

In addition to the administration of analgesia and anesthesia, the anesthesiologist supervises the administration of restorative fluids and drug therapy as indicated by the changing medical status of the mother. Moreover, he assumes the care of the newborn infant so that the airway is cleared immediately, the stomach is aspirated, and good oxygenation is secured promptly and continued until the infant breathes spontaneously. During the postpartum period daily rounds are made and the anesthesiologist takes an active part in the prevention and treatment of postanesthetic complications and in the management of respiratory problems in the infant. We deem it especially important to see these patients daily until they leave the hospital because this is not only proper anesthesiologic practice but also good public relations.

PUBLIC RELATIONS PROGRAM

In order to improve further our relations with obstetric and surgical patients, we have embarked on a long-range public relations program that requires the constant and unrelenting efforts of every member of the group, the obstetrician or surgeon, the nursing staff, and the hospital administration. The obstetricians have cooperated by informing patients about the department and emphasizing the advantages of medical anesthesia. The hospital administration also mails a booklet of information concerning the department of anesthesia along with other literature that is intended to inform the prospective patient about the hospital. Great emphasis is laid to proper deportment of the anesthesiologist during the postpartum visit to make the patient realize that he is a member of the obstetric team. It is a strict rule among our group that attending anesthesiologists avoid visiting patients in hospital garb but must wear street clothes, lest the patient mentally will categorize the anesthesiologist as one of the house staff. Moreover, every postpartum patient is seen by the director of the department of anesthesiology or one of the attending anesthesiologists. In addition to improving public relations, it affords us an excellent opportunity to obtain a perspective of our efforts.

Another important facet of our public relation program involves the frequent orientation of the nursing staff and the nonprofessional hospital staff, particularly those who work in the front office. With the cooperation of the director of nursing, we have been able to indoctrinate the student and graduate nurses with the importance of medical anesthesia. Our efforts in this regard are reflected by the excellent cooperation we obtain in the obstetric pavilion and on the wards. The nursing staff manifests a similar attitude and respect toward the members of our department as they do toward the obstetricians and thus imbues the patient similarly.

With this program we have encountered very little difficulty in making the patients reealize that they have received a specialized service. Moreover, this has facilitated the transition from hospital practice to private practice of anesthesiology. Patients are billed directly on a fee-for-service basis by our office, which is in a medical center located away from the hospital. All patients are sent a bill except those who have insurance with two local medical groups. We charge a basic fee for the administration of anesthesia for the second and third stage of labor. This fee, which is based primarily upon the fact that a professional service has been rendered, was decided upon by determining the duration of the average obstetric anesthesia in the hospital and what it would have cost the patient in former years when the anesthesia was administered by technicians. If prolonged blocks are administered during the first stage of labor, the fee is increased slightly for each additional hour, with a ceiling charge equivalent to four hours of anesthesia. In addition, the patient is charged a very nominal fee by the hospital for the use of drugs and equipment. At the present time it costs the patients an average of $5 more than it did for technician anesthesia. We feel that this augmentation in the over-all obstetric anesthesia fee, which represents an increase of less than 2% of the total bill in the delivery, is insignificant in view of the better services rendered and must be considered as inexpensive insurance for the added safety to mother and infant. This fact is further emphasized when it is realized that the majority of the obstetric patients pay less for their anesthesia than a patient who receives anesthesia for an appendectomy.

The fee is the same whether the attending anesthesiologist or resident gives the anesthetic. This was done in order to standardize our fees as much as possible. To obviate criticism that might be made because the patients who receive an anesthetic administered by the resident alone are billed by the group, several facts may be mentioned. Firstly, the attending anesthesiologist is available for consultation call at all times. Secondly, all expenses incurred with the residency training program, including the resident's stipend, room and board, books, and expenses involved in attending meetings and obtaining guest lecturers, are paid by the group.

COMMENT

It is generally conceded that the contribution made by the rapidly developing science of anesthesiology constitutes one of the most important factors that has made possible the great advances in surgery during the past quarter of a century. Unfortunately, the same cannot be said in regard to obstetrics. While it should be readily admitted that many of the improvements in anesthetic practice have been applied to obstetrics, the contributions in this field have not been commensurate with the progress made in anesthesiology. This is especially true in regard to the administrator, a factor that, in the final analysis, is the most important to be considered. Most of the interest in obstetric anesthesia has been focused on refinement in techniques and producing better agents, but relatively little has been written or done to encourage the development of expert administrators. It serves little purpose to discuss the selection of methods of anesthesia unless there is a corresponding effort to encourage the application of these methods with the best judgment and greatest skill. A further reduction in the mortality and morbidity in obstetric anesthesia will depend to an increasing extent on the ability of the anesthesiologist and his active participation on the obstetric team to the same extent as he participates on the surgical team.[1f] Both the anesthesiologist and obstetrician must share the blame for the fact that this is not the case at the present time.

The obstetrician has been at fault for accepting, in many instances, the barest minimum of anesthetic service at the hands of the most uninformed and the least useful person in the delivery room, whereas in his gynecologic practice he would be satisfied only with the services of an expert anesthesiologist.[1e] The obstetrician should encourage and even demand that the department of anesthesiology be organized to give the obstetric service expert administration of any type of analgesia or anesthesia, any time it is desired. If anesthesiologists cannot offer such techniques as caudal, peridural, or subarachnoid blocks as a regular service, it is inevitable that they will be unavailable when most needed. The obstetrician deserves the benefit of the anesthesiologist's skill in the management of patients whose lives are threatened by hemorrhage, toxemia, or other complications, as well as in those abnormal conditions that might interfere with the lifeline of the fetus, such as prolapsed cord, prolonged labor, eclampsia, dystocia, and premature separation of the placenta. Moreover, he should derive the benefit of the anesthesiologist's skill in the management of asphyxia neonatorum and expert knowledge of depressant drugs and be able to rely on the latter to observe and evaluate the many and varied regimens of sedatives, narcotics, and amnestic drugs recommended for the first stage of labor. The obstetrician should have the interested and informed cooperation of the anesthesiologist so that he may avoid the many occasions for hazardous synergistic combinations that exist between obstetric drugs and anesthetic agents.

The provision of such services is a responsibility of the specialty of anesthesiology. Anesthesiologists must devise ways and means of satisfactorily solving the problem of providing round-the-clock anesthesia service to the obstetric department. One of the best methods of discharging this important obligation in a private hospital is for the anesthesiologists to practice as a well-organized group on a physician-patient, fee-for-service basis. Several years of experience with this form of practice have demonstrated that everyone involved benefits therefrom. The patient is provided with expert anesthesia at reasonable fees while the obstetrician may expect more efficient and more capable service and patient care. The availability of such expert services on a 24-hour basis facilitates the hospital administration and enhances the reputation of the hospital, thus greatly improving its over-all care. The most significant advantages accruing to the anesthesiologist working within the framework of such a group are that he is able to provide better services and to have more regular hours with a definite call schedule to allow time for study, teaching, and recreation. It is true, of course, that there is still a shortage of anesthesiologists and such an arrangement as herein described is obtained by an evolutionary process that requires the concerted effort and cooperation of anesthesiologists, obstetricians, hospital administrators, and the nursing staff. During the transition period, it may be necessary to use personnel other than trained physicians. However, the ultimate goal must remain the coverage of the obstetric department at all hours by expert anesthesiologists.

SUMMARY AND CONCLUSIONS

In recent years there has been an increasing awareness of the importance of anesthesia in obstetrics. Teamwork and cooperation between anesthesiologist and obstetrician are the prerequisites for optimal results in producing adequate pain relief for the mother, without detrimental effect to the infant. It is essential, therefore, that anesthesiologists take a more active part in the management of patients in labor notwithstanding their relative scarcity. It is an obligation that rests squarely on the shoulders of this group to devise ways and means of providing the anesthetic services that the patient, her infant and the obstetrician deserve. The private group practice of anesthesiologists is one of the best means of attaining this goal. The most important advantage of such a group is that it can offer complete, expert anesthesiologic care In addition to the selection and administration of the anesthetic best suited for the individual patient, the anesthesiologist offers his expert service for the care of th newborn infant during the neonatal period, especially i resuscitative measures are necessary. In addition, he ca assist the obstetrician during the postpartum period t prevent or treat complications that may be related to th anesthetic. Moreover, the anesthesiologist's extensiv experience with subnormal states of respiration and circulation may be applied to the safeguarding of the newborn infant during the critical first 24-hour period.

CONTRIBUTIONS OF THE DOCTOR OF PHYSICAL MEDICINE AS A HOSPITAL DIAGNOSTICIAN

Leslie Blau, M.D., Buffalo

The doctors who pioneered in the field of physical medicine long recognized the significant role they could play in medical practice, and they fought for recognition. They knew that treatment with physical medicine and the diagnosis and management of disease must be in expert hands for proper utilization and development.[1] They realize what a broad knowledge a doctor of physical medicine required. Consequently, they had to establish standards. Their effort was culminated in the organization of the American Board of Physical Medicine and Rehabilitation, and thus the recognition of this field of endeavor as a clinical specialty was accomplished. The requirements for the examination in physical medicine cover a broad field of medicine, surgery, and allied fields, such as biophysics, because the doctor will be called upon to deal with every type of case.[2] The physician practicing physical medicine wa designated the physiatrist by the Council on Physica Medicine of the American Medical Association at it annual meeting in 1946.[3]

MAIN FUNCTIONS

The principal functions of the physiatrist in a genera medical and surgical hospital are administration, diagnosis, therapy, and research. In addition, he coordinates the activities of ancillary services in a total effor to prepare the patient for a successful psychosocioeconomic adjustment following his discharge from the hospital. The ideal situation is when these functions are well blended. It does not mean that such a doctor could not have a primary interest; however, since he is representing a clinical specialty, any head of a department of physical medicine who will neglect his clinical functions for others, such as administration or research, leaving diagnosis entirely to the referring physician and therapy to the therapist, will not only misrepresent the specialty but may also do harm to the patient. It happens that physicians in charge of departments of physical medicine and rehabilitation overemphasize one function, neglecting the others. Some act purely as

administrators, and all they do for the patients is correlate for them the activities of the professional and subprofessional services, with no contribution of their special skills. They almost degrade themselves to the role of a correlator[4] and poorly represent a specialty that has so much to offer. There are others who go so far as to profess that the department of physical medicine is designed only for therapists to carry out blindly the referring doctor's prescription and that the role of the physiatrist is principally only research with some administrative duties. Of course, such a contention is completely fallacious. Treatments administered by therapists without the close and direct supervision of a doctor skilled in the specialty will usually result in the routine administration of "heat, massage, and exercise." The physiatrist understands the fine effects and minute differences of physical agents and is able to apply this knowledge in correlation with his clinical findings. He can make changes in modalities and even in the entire treatment regimen according to the physical and mental condition of the patient without delay.

The purpose of this paper is to stress the role of the physiatrist as a diagnostician. He helps the referring physician by utilizing his clinical acumen as well as the modern electrodiagnostic instruments that are at his disposal. Leaders in physical medicine recognize the importance of accurate diagnosis of the condition of patients referred to the department of physical medicine for treatment, and for that reason they advocate that referral diagnoses should not be accepted unquestioned.[5] A large percentage of patients are referred to the department of physical medicine for the treatment of diseases that are diagnosed tentatively at the time of admission to the hospital or shortly afterward, pending a thorough study. The aim of referral is usually symptomatic relief with "a little heat, massage, and exercise." The random selection of physical agents at our disposal may not only be harmful but actually catastrophic. A case history, as an example, will illustrate this point, and other points will be raised in connection with the description of other case histories.

REPORT OF CASES

Case 1.—A 55-year-old man was referred to the department of physical medicine and rehabilitation in November, 1950, for the treatment of peripheral neuritis with the following additional comments: "back pain, probably weight bearing or on postural basis." Physiatric examination revealed the following positive findings: The patient was obese, and his posture was poor, with severe relaxation of plantar arches, hallux valgus bilaterally, and round shoulders. There were moderate trophic changes of his feet, including toe nails. Pedal pulses could not be palpated. Oscillometric readings of legs were only trace and of the ankles and feet, zero. This examination indicated that patient's symptoms were caused primarily by arterial occlusion and perhaps secondarily by ischemic neuropathy of his legs. Random administration of heat and simply accepting the referral diagnosis of "peripheral neuritis" could have easily precipitated gangrene.

Another example will illustrate that postponement or no physical treatment may be the best course one can take for a patient referred to the department of physical medicine and rehabilitation.

Case 2.—A 64-year-old man was referred to us in October, 1950, for treatment of "recent right cerebrovascular accident with spasticity of left arm." Questioning of the patient at bedside by the doctor of physical medicine revealed that the patient fell and hurt his shoulder, and there was also some indication that he was under the influence of alcoholic beverages at the time of the supposed cerebrovascular accident. It was further established that no active or passive relaxed movement was possible in the left shoulder joint, and elbow movements were also restricted due to acute pain in the shoulder. The examiner suspected fracture of the humerus and recommended postponement of physical treatments until x-ray findings were known. Subsequently, it was revealed that patient had a fracture of the neck of the humerus. A hanging cast was applied after the patient's transfer to the orthopedic section. The patient became ambulatory in two days with no residue of any central nervous system insult. The diagnostic acumen of the physiatrist was obviously very contributory in this instance, and prompt initiation of treatments upon referral might have done great harm to the patient.

Frequently patients referred to the department of physical medicine for treatment are treated too long with no regard for expense and improvement. Physical medicine is oftentimes accused of unnecessary treatments. Such practices can be counteracted by the physiatrist implementing periodic reevaluations and by a standing order to therapists to report intolerance to treatment. A case history will illustrate this point.

Case 3.—A 23-year-old man was referred to the department of physical medicine and rehabilitation in January, 1951, for treatment of lumbosacral strain with diathermy, massage, and hyperextension back exercises. At that time patient was not examined by the physiatrist for the sake of expedience and because suggested treatments seemed adequate. One week later the therapist reported that patient was unable to tolerate hyperextension exercises. I went to see him when he was on the treatment table. I noted an old empyema scar. On slight touch of the scar, the patient became very belligerent and shoved the examiner's hand off. Watching the treatment, I found that he was totally uncooperative. An examination revealed the following history: The patient alleged pain across his back without radiation. He claimed that he was hospitalized the previous year. A myelogram was done after which he was discharged without treatment. He alleged pain since 1946 (five years) after an amphibious landing. Examination also revealed the patient was extremely jittery. Horizontally extended hands showed coarse tremor. His face looked tense and sunken. The empyema scar in the right axillary was very well healed and tender, but his reaction was not consistent to palpation. The patient alleged acute tenderness on slight touch of the lumbar muscles and spine. He flexed his body with knees extended, reaching 30 in. from the floor. Other movements were also extremely guarded. Paravertebral muscles were relaxed. Heel jar test elicited no pain, although the patient did not carry it out properly. It was the impression of the examiner that even though the patient might have recurrent lumbosacral strain, there was a 100% functional overlay. Psychiatric evaluation was recommended. The physician attending the patient was contacted, and physical treatments were discontinued. It was subsequently revealed that neuropsychiatric examination resulted in the establishment of the diagnosis of "conversion hysteria," and shock therapy was recommended.

The physiatrist is in a position to assist his colleagues in their diagnostic efforts by the utilization of modern electrodiagnostic instruments such as the constant current impulse stimulator developed by Golseth and Fizzell[6] and the electromyograph. The former permits us to gather important data on muscles by determining of the strength-duration curve, chronaxy, and repetitive, galvanic-tetanus, and rheobase ratios. The latter records the action potentials that develop in skeletal muscles. The clinical interpretation of this pool of information with correlation of clinical findings oftentimes furnishes us with convincing diagnostic clues that could not be arrived at by purely clinical means. The following case history will illustrate this point

		Cathodal tetanus ratio	3.1	Rheobase ratio	1.7

* Chronaxy in milliseconds, 5; no discontinuities; faradic response, present. Chronaxy by another method (rheobase 15 volts), 10 milliseconds.

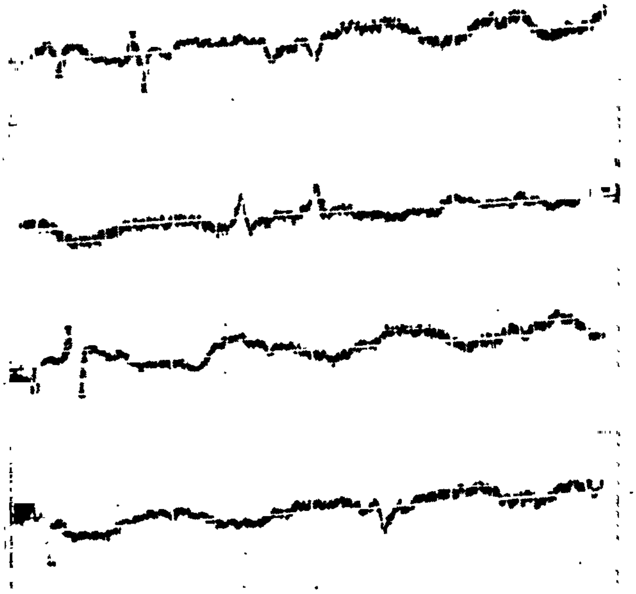

Fig. 1.—Electromyographic tracings of the middle deltoid muscle at rest: spontaneous diphasic and monophasic action potentials of some 20 to 50μ in amplitude and 2 to 3 milliseconds in duration. These are fibrillation potentials typical of lower motor neuron involvement.

Case 4.—A 41-year-old male was referred to the departmen of physical medicine and rehabilitation Oct. 17, 1950, for trea ment of "bursitis, right shoulder." The patient gave a histor of "pain in the right shoulder, down to arm" of two and on half weeks' duration. He also complained of numbness in a his fingers. It was obvious that the patient favored the right upp extremity by holding the arm in acute adduction. Function muscle examination revealed "T" to "P" strength of the deltoi latissimus dorsi, teres minor, and infraspinatus. There was on 20 degrees and 30 degrees of actual limitation in the should joint. Tapping of the deltoid revealed fasciculation. Reflexes we normal, and there were no sensory changes to pin prick. Ina much as the referral diagnosis of bursitis did not satisfy t examiner, further studies, such as cervical spine x-ray and spin fluid examination, were recommended and proved to be norm The referring physician consulted two neurologists, and bo were of the opinion that the patient's symptoms were caused disuse. Electrodiagnostic studies confirmed the original impr sion of the physiatrist that the right deltoid muscle was tr paretic. The table lists the information gathered with the co stant current impulse stimulator and the clinical interpretati of the examiner. The examiner's impression was that the elect cal pattern indicated lower motor neuron involvement. T impression was of a partial lesion (i. e., part of the fibers n mal, part denervated); hence, the muscle still responded to t faradic current. The long S-D curve, with a tilt of the strengt frequency ratio toward a 1:2:3 ratio, suggested a demyelinati process. Figures 1 and 2 are samples of electromyographic tra ing that clearly show numerous action potentials in the resti middle deltoid. These are fibrillation potentials. In the light such convincing evidence, the diagnosis was changed to acu neuritis with paralysis, etiology undetermined. The patient w subsequently treated on the basis of this diagnosis; he improv and was discharged.

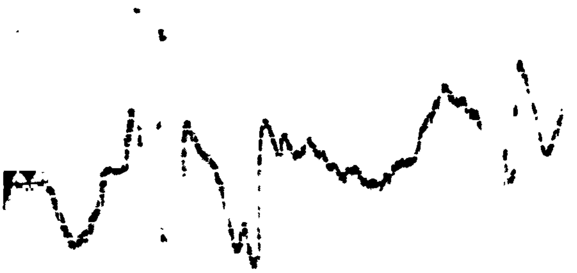

Fig. 2.—Electromyographic tracings of the middle deltoid muscle effort: simple and polyphasic potentials of 150 to 200μ in amplitude a 3 to 5 milliseconds in duration. These potentials are characteristic weak or paretic muscles.

SUMMARY

The physiatrist has an important role as a diagno tician in a general medical and surgical hospital. Med cal literature [7] points out that the physician trained i physical medicine, by virtue of his training and exper ence, must have more detailed knowledge of certain dis eases such as arthritis, peripheral vascular disease poliomyelitis, peripheral nerve injuries, cerebral pals and spinal cord injuries. I feel that many members o the medical profession are not aware of the help trained and qualified physiatrist can offer general prac titioners and many specialists in diagnosing disease and treating their patients.

PLACEMENT OF REHABILITATED PATIENTS

A. Ray Dawson, M.D.
and
Richard N. Anderson, M.A., Richmond, Va.

It is our purpose to make a progress report on a joint undertaking entered into by the vocational rehabilitation service, Department of Education, commonwealth of Virginia, and the McGuire Veterans Administration Hospital, Richmond, Va., wherein the commonwealth detailed to McGuire a state vocational counselor on a full-time basis. Thus the full facilities of the state in the areas of vocational counseling and job placement were brought to the veteran at the earliest practical moment in his illness or after his injury. As it was determined that we were to make a pilot study, prior approval was obtained from the central office of the Veterans Administration and the office of vocational rehabilitation, Department of Health, Education, and Welfare. The office of vocational rehabilitation underwrote the salary of our counselor for a trial period as a part of its research program. The Veterans Administration has had in operation for some time a well-developed and quite effective program of vocational counseling and job placement. However, the Veterans Administration's program was designed for and was primarily intended for persons with service-connected cases and was not expected to render adequate coverage to those with non-service-connected cases. The activities of the state in this study were limited to non-service-connected cases.

TYPE AND DISTRIBUTION OF CASES

In the late 1940's it became apparent that, while medicine and surgery were reaching a high degree of effectiveness in saving lives and restoring function, we in rehabilitation could not carry out our responsibilities without state aid in handling non-service-connected cases. Although the non-service-connected case load was not large volumewise, the cases were predominantly of the "dread disease" or "catastrophic injury" category. As will be seen later, numerically presented, we were dealing with paraplegic, psychotic, tuberculous, and orthopedic patients, patients with acute and chronic neurological conditions, and a few patients with general medical and surgical conditions. These were patients who required maximum rehabilitation efforts and careful job-study placement if rehabilitation to employability was to be accomplished. For a while we had the services of a state counselor on an itinerant basis. This approach was found to be inadequate. It failed in the two most important areas: first, that of early counseling, and, second, complete teamwork follow-through. We, therefore, requested of the commonwealth that a full-time vocational counselor be detailed to our hospital, and this was done in May, 1951. For our study we have selected the 18 month period between July 1, 1951, and Dec. 30, 1952, in which there were 400 cases. A follow-up study was made the first three months of this year; i. e., Jan. 1 through March 31, 1955.

Although it was originally not the purpose of this paper to discuss the therapeutic value of vocational counseling, this was such a striking feature that we wish to comment on it. Most of these patients were in their late 20's or early 30's; they had been discharged from the service a matter of three to five years, and they had young families. By and large, they were just getting started in a business or a vocation when a catastrophe struck them. Some of the patients were so overwhelmed as to be unable to fight their way back to vocational adjustment. In our study we used the term "lack of motivation" to describe this condition. It is not a term that we prefer, because we believe that we are dealing with such factors as fear, resentment, self-pity, and mother fixation. Early vocational counseling combined with other rehabilitation activities did much to prevent these emotions from developing a fixed pattern of action. There are certain additional features of this group that should be mentioned. 1. None of these patients was sent to the hospital for physical restoration in connection with an already planned vocational objective. 2. None of these patients was able to return to his former employment without modification of working conditions. 3. A few were able to return to related or similar employment. 4. A few patients were reemployed by their former employers in different job classifications.

The table shows the general distribution of cases and certain totaling data. This table is divided into three sections. The section on cases gives the number of patients worked with and certain basic data concerning them. The section on patients who were rejected gives the three reasons for rejection: (1) service-connected disabilities, (2) lack of motivation, and (3) rehabilitation medically unfeasible. The section on status shows the number of patients accepted for training and/or job placement and gives the outcome of efforts directed to this end. The type of patients that we were working with is shown in column 1. The first five categories of patients—i. e., neurological, tuberculous, psychiatric, paraplegic, and poliomyelitic—by their very nature present major rehabilitation problems. In addition to this, one of us (A. R. D.) would like to comment on the severity of disease or injury seen in a Veterans Administration hospital as compared with a similar group seen in a large state or municipal hospital. In those categories of conditions where patients can be adequately treated by office procedures or at most a few days of hospitalization, the person with a non-service-connected case does not usually come to a Veterans Administration hospital. It is those among this group with severe cases and those requiring prolonged hospitalization who seek Veterans Adminis-

Chief, Physical Medicine and Rehabilitation Service, McGuire Veterans Administration Hospital, and Associate Professor of Clinical Physical Medicine, Medical College of Virginia (Dr. Dawson); Director, Division of Rehabilitation and Special Education, State Department of Education (Mr. Anderson).

Read before the Section on Physical Medicine and Rehabilitation at the 104th Annual Meeting of the American Medical Association, Atlantic City, June 9, 1955.

tration hospital care. This is best exemplified by our findings in the neurological and general medical groups; rehabilitation of 31 of 49 neurological and 16 of 31 general medical patients was finally found to be unfeasible for medical reasons.

Number of Patients.—Column 2 gives the total number of patients divided into categories and reflects the nature of our hospital and the type and volume of problem that presents itself to us. As can be seen from the total, we have a large neurological service, a fairly large psychiatric service for a general hospital, and a large paraplegic service, as well as a poliomyelitic service with respirator facilities.

Mean Age.—Column 3 gives the mean age of the patients. We have commented on this before; however, we would like to point to the higher age levels found among neurological and medical patients. This is even more striking when we study the age distribution pattern and find such a large number of patients in the 50 to 65 age groups.

Out-of-State Cases.—Columns 4 and 5 compare the patients from out-of-state to those from the state, with the largest out-of-state group being paraplegic. We did not find the same degree of accuracy in following the out-of-state patients that we found within the state of Virginia; this was perhaps due to distance and multiple authorities. State versus nonstate residence of patients had little effect on our findings. In the actual vocational counseling and job placement of the patient we were much pleased with the full cooperation that we received from out-of-state authorities. We believe this condition reflects the high degree of efficiency the vocational rehabilitation services have attained in all of the states with which we cooperated.

Reasons for Rejection.—Columns 6, 7, and 8 with their percentages depict the reason why patients were rejected for training and/or job placement. Column 6 shows how many patients with service-connected conditions were rejected. If a patient's claim for service connection was adjudicated as "service connected" while the state counselor was working with him, this patient was immediately turned over to the veteran's counseling service and the case folder was removed from the files of the state counselor. As can be seen in the table, there were 43 such patients, with the largest number among the paraplegics. Column 7 shows the number and percentage of patients rejected for lack of motivation. We have found that lack of motivation has not shown itsel percentagewise to be the big block to rehabilitation tha could be expected. In addition, we believe that as w learn more about the emotional components accompanying severe disability many of the associated factors ma be extracted and found amenable to treatment. We wis to reemphasize that our findings lead us to believe tha early rehabilitation endeavors and early vocational counseling had much to do with preventing frustration an dependency patterns from developing. Column 8 concerns the cases in which rehabilitation was medically unfeasible. Because of factors already enumerated in th discussion, we found this element to be particularly hig in the medical and neurological groups; however, for th remainder of our study, medical unfeasibility was no above what would normally be expected. A total of 17 or 44% of the patients (i. e., columns 6, 7, and 8) we rejected for training and/or job placement for one the reasons enumerated above, leaving 224 patien (column 9) who were accepted for training and jo placement.

Results of Accepted Cases.—Of the group of 224 wh were accepted, 36 (column 10) are now hospitalized, (column 11) are in training, and 38 (column 12) coul not be followed up at the time this paper was prepared Two (column 13) are known to be deceased. Five (column 14) have employment pending. Column 15 reveal that 134 or 59% of those accepted are now employe and earning $305,391 (column 16) per annum, an average of $2,279 a year.

Results of Cooperative Program Between State Rehabilitation Service and McGuire Veterans Administration Hospital, July 1, 1951, to Dec. 30, 1952

EFFECT OF COUNSELING

One might logically ask how many of these people would have found employment had there not been a vocational counseling service available. This, of course, is a question that constantly plagues us. There is no ready answer, but we do know from clinical experience that before having a full-time counselor for this group of persons with non-service-connected cases very few of them found suitable employment and that as soon as we had the full facilities of the commonwealth of Virginia at our command a changed picture became evident almost at once. We are convinced that early rehabilitation and complete vocational counseling plus job placement pay handsome dividends in happiness and financial returns.

RESULTS WITH PSYCHIATRIC GROUP

We had hoped to analyze our findings in some detail in relation to each category, but as space will restrict us to a few remarks relative to only one category, we would call attention to the psychiatric group, which includes the psychotic. The results of work with these patients both during this study and since Dec. 30, 1952, has been most gratifying. There seems to be such a tendency to shy away from job-placing the patient who has been psychotic that we wish to emphasize the good features of handling this group. It will be noted that of the 75 handled, 40 were finally accepted for training and/or job placement; of the 40 accepted, 33 are now known to be employed. They are making $93,245 annually, with an average yearly income of $2,825, which is some $600 better than the group average. It has been our experience that when both the employees and the employers are adequately counseled regarding what can be expected in a job situation much of the cloudiness surrounding employment of persons who have been psychotic disappears. To place adequately a person who has been psychotic we must take into consideration his basic personality pattern and relate to it his future working conditions. Such things as noise of work, need to meet the public versus lack of it, and pressure to make decisions versus repetitive work processes become major factors in his adjustment. Among the 40 persons accepted, psychiatric diagnoses varied from mild conversion reaction to psychosis requiring lobotomy. In fact, two of the employed persons are patients in whom lobotomy was done. The largest number, as would be expected, were schizophrenic. We believe this group deserves more attention than we have given it in the past.

One of us (R. N. A.) would like to emphasize that in dealing with severely disabled patients there must be the closest cooperation between vocational counseling, job placement services, and the medical services. In addition, there must be medical follow-through to the actual working situation and, at times, medical counseling of the patient and the employer after the patient is on the job.

SUMMARY

Over a period of 18 months 400 severely disabled veterans were studied and treated in a joint project of the physical medicine and rehabilitation service and the vocational counseling service, McGuire Veterans Administration Hospital, Richmond, Va., and the vocational rehabilitation service, Department of Education, commonwealth of Virginia. The study was concerned chiefly with the 357 persons whose disabilities were non-service-connected. Follow-up data were collected three years after the close of the test period. Of the 357 patients with non-service-connected disabilities, 133 were not accepted for job placement because of various reasons. Of the 224 accepted, 134 or 59.8% were gainfully employed at the time of the follow-up; their average annual salary was $2,279 per year. The earlier in the patient's disability that rehabilitation and vocational counseling are begun, the better are the therapeutic results, physical and psychological, and the better the vocational rehabilitation. In this study, the results with psychiatric patients, including psychotic, have been gratifying. Of 40 such patients accepted for job placement, 33 or 82.5% were gainfully employed at the time of the follow-up. Their average annual earnings were $2,825, or better than the average for the whole group. Close cooperation between the physician, vocational counselor, and job placement service is an essential feature in dealing with the severely disabled.

3416 Wythe Ave. (Dr. Dawson).

CLINICAL NOTES

DIAGNOSTIC ERRORS DUE TO HIGH SPINAL FLUID LEUKOCYTE COUNT IN SUBDURAL HEMATOMA

William E. Schatten, M.D.
and
Frank E. Nulsen, M.D., Cleveland

There have been numerous reports of subdural hematoma since the condition was first described as an entity by Putnam and Cushing in 1925. However, the white blood cell reaction of the meninges in this disorder has been mentioned in very few reports and the spinal fluid white cell count has not been given consideration as a finding that might lead to an error in diagnosis. The consensus of opinion has been expressed in an early article by Munro,[1] who concluded that exploratory trephination of the skull was indicated whenever patients showed progressive mental changes or neurological signs and the cellular count of the cerebrospinal fluid ruled out meningitis. Others have stressed that neither failure to elicit a history of head trauma nor the finding of normal or reduced spinal fluid pressure eliminates subdural hematoma as a cause for progressive deterioration in behavior and responsiveness. In the following two cases of subdural hematoma an atypical finding, a leukocytic reaction in the spinal fluid, led to an erroneous diagnosis of meningitis and operative intervention was therefore delayed.

REPORT OF CASES

CASE 1.—A 13-year-old Negro boy was admitted to the neurosurgical service at the Hospital of the University of Pennsylvania on Nov. 13, 1948. This boy was considered by his guardian to have been in excellent health until two weeks prior to admission, when he began to complain of headache, refused to go to school, and ate poorly at home. This headache increased in severity and became associated with vomiting as well as increasing lethargy and confusion. He was rushed to the hospital when it became

---

From the Division of Neurosurgery, Department of Surgery, Western Reserve University School of Medicine and University Hospitals.

Dr. Francis C. Grant gave permission for inclusion of case 1.

[1] Munro, D.: The Diagnosis and Treatment of Subdural Hematomata: A Report of 62 Cases, New England J. Med. **210:** 1145-1160, 1934.

almost impossible to arouse him. Examination showed a well-nourished young male who lay quietly in bed. He would respond to simple commands and say a few words with persistent urging. He responded to painful stimuli by moving his extremities in symmetrical fashion and by grimacing symmetrically. There was striking nuchal rigidity with a bilateral Kernig's sign. The optic fundi showed venous engorgement without definite papilledema. The pupils were equal in size, and there was limitation in the lateral movement of each eye, suggesting bilateral sixth nerve involvement. The extremities showed reduced tendon reflexes with bilateral Babinski signs. His temperature was 100 F, pulse rate 60 per minute, respiration rate 16, and blood pressure 130/88 mm. Hg.

Lumbar puncture revealed slightly xanthochromic fluid under more than 600 mm. pressure in the reclining position. Despite the elevated pressure, the Queckenstedt maneuver was employed to demonstrate open manometrics. The immediate blood cell count showed 140 leukocytes per cubic millimeter (90% lymphocytes) and no erythrocytes. Subsequent chemical studies showed that this fluid had a sugar content of 55 mg. per 100 cc. Neurosurgical consultation was promptly requested. The central nervous system depression with increased intracranial pressure, in combination with signs of meningeal irritation and a spinal fluid lymphocytosis, was considered consistent with tuberculous meningitis, but brain abscess remained a possibility. Skull x-rays showed no definite abnormality (the pineal gland was not visualized). A chest film showed no abnormalities. Occipital trephines were then accomplished with the patient under local anesthesia in order to give access to the ventricles. The cortex bulged on opening of the dura on each side. Each lateral ventricle was readily encountered with a cannula and fluid escaped under moderately increased initial pressure with each ventricle draining about 15 cc. Since this ventricular estimation gave the impression of no ventricular enlargement or asymmetry to suggest a large mass lesion and since the patient's condition seemed, if anything, improved, it was decided to postpone introduction of air for ventriculography until morning, with the patient observed closely meanwhile. Three hours later, without any previous fluctuation in vital signs or responsiveness, the patient abruptly died.

Autopsy revealed a 200 cc. subdural collection of fluid on the left consisting of dark liquefied blood enclosed in a thin yellow-stained membrane. Its posterior limit stopped just short of the left occipital trephine. The collection was of sufficient size to be consistent with critically increased intracranial pressure. There were associated herniations of the left uncus through the incisura and of cerebellum through the foramen magnum as the probable explanation for respiratory cessation. Subsequent study revealed no lesions in the brain parenchyma except for a few petechial hemorrhages in the pons. The meninges showed no inflammatory reaction on microscopic study.

Case 2.—A 46-year-old Negro female was brought to the emergency ward of University Hospitals of Cleveland on April 4, 1954, in a semiconscious state. The patient had been struck on the head approximately 48 hours prior to the time of admission with no resulting loss of consciousness. Twenty-four hours later, she became very quiet and did not respond well to requests. She was, however, able to ask for assistance to the bathroom and for water to drink. She remained in bed most of the time during the 12 hours preceding admission.

Physical examination revealed a well-developed, moderately obese Negro female who responded slowly to simple commands. Temperature was 39.2 C, pulse rate 100 per minute, respiration rate 28, and blood pressure 180/90 mm. Hg. There were no lacerations of the scalp or face. There was conjunctival hemorrhage and ecchymosis of the eyelid and surrounding soft tissue of the right eye. There was moderate nuchal rigidity, with a positive Kernig's sign. Lumbar puncture revealed xanthochromic fluid under 340 mm. pressure in the reclining position. The immediate blood cell count showed 6,850 leukocytes (100% polymorphonuclear leukocytes) and 5,050 erythrocytes per cubic millimeter. Subsequent chemical studies showed that this fluid had a sugar content of 55 mg. per 100 cc. and a protein content of 220 mg. per 100 cc. Gram and Ziehl-Neelsen stains of the spinal fluid did not reveal the presence of bacteria. The peripheral leukocyte count was 10,100, with a normal differential count.

Skull roentgenograms showed no evidence of a fracture, and the pineal gland could not be identified. The signs of meningeal irritation and the marked polymorphonuclear leukocyte response in the cerebrospinal fluid were considered strong evidence for *acute bacterial meningitis*. It was decided to watch the patient closely and to treat her with penicillin and streptomycin. Lumbar puncture performed 12 hours after admission revealed xanthochromic fluid under 240 mm. pressure. There were 2,028 leukocytes per cubic millimeter (98% polymorphonuclear leukocytes). Subsequent chemical studies showed that this fluid had a sugar content of 53 mg. per 100 cc. and a protein level of 220 mg. per 100 cc. Twenty-four hours after admission, the patient's pulse suddenly decreased from an average of 104 to 80; the other vital signs remained stable. At that time it was also noted that there was slight dilatation of the right pupil and conjugate deviation of the eyes to the right. The following morning it was believed that the patient was becoming less responsive. Lumbar puncture at that time showed xanthochromic cerebrospinal fluid with a leukocyte count of 520 (61% polymorphonuclear leukocytes), a sugar level of 67 mg. per 100 cc., and protein level of 264 mg. per 100 cc.

A relatively dilated right pupil and decreasing responsiveness were considered indications for trephination. This was performed 36 hours after admission. A subdural hematoma was encountered in right frontal and parietal trephines, and a considerable amount of semisolid clot was evacuated by through-and-through irrigation. The patient's condition improved only temporarily. Ventriculography was therefore performed three days later. This revealed a displacement of the ventricular system toward the left, with the third ventricle being centered 1.2 cm. from the midline. Accordingly, craniotomy was performed immediately and an extensive solid hematoma was evacuated from the right subdural space. This lay inferior to the previous burr holes, reaching maximum thickness over the temporal lobe. The patient had a satisfactory recovery postoperatively and she was discharged 25 days following craniotomy. The only residual neurological change was a left homonymous hemianopsia. Spinal fluid leukocytes were reduced to 2 mononuclear leukocytes per cubic millimeter, and she was afebrile by the eighth postoperative day. Eight months postoperatively the patient was managing her household effectively and was not consciously disabled by her residual difficulty in seeing toward the left.

COMMENT

In the first case, in which there was a history of progressive deterioration with critical depression of the central nervous system and increased intracranial pressure, chronic subdural hematoma was considered improbable because of the cellular reaction in the spinal fluid. Trephination was carried out, but in a fashion too limited to exclude this possibility with the unfortunate postponement of ventriculography since the patient's condition did not appear critical. His sudden decompensation to increased intracranial pressure and the cerebellar pressure cone found at autopsy may well be related to the lumbar puncture and the Queckenstedt test carried out in the face of increased intracranial pressure. Nevertheless, had the presumption of a subdural hematoma not been discarded because of the cerebrospinal fluid blood cell count, the boy in this case would almost certainly have been saved. In the second case, surgical intervention was delayed 36 hours because the spinal fluid leukocyte count, which was greater than the spinal fluid erythrocyte count, was believed to be too high to represent an aseptic meningeal reaction. Happily, previous experience now dictated that a clinical situation consistent with subdural hematoma should be treated as such in disregard of spinal fluid findings, so that operation was undertaken before irreversible damage occurred.

Let us now consider possible explanations for this unusual cellular reaction in subdural hematoma. Merritt and Fremont-Smith,[2] in a study of the spinal fluid leukocyte count in 54 cases of acute subdural hematoma, reported one case in which there was a marked aseptic meningeal reaction, there being 2,400 polymorphonuclear leukocytes per cubic millimeter. In the same report, autopsy-proved cases of intracerebral hemorrhage were reviewed and the greatest aseptic meningeal reaction was represented by a spinal fluid white cell count of 3,600 leukocytes per cubic millimeter, 90% being polymorphonuclear leukocytes. Hammes,[3] in a study of 53 autopsy-proved cases of ruptured intracranial aneurysm with subarachnoid hemorrhage, concluded that the leukocyte reactions in the meninges usually increased progressively until the third day after bleeding, but at no time was a polymorphonuclear leukocyte response comparable in intensity to the reaction in acute bacterial meningitis.

The low-grade cellular reaction in the spinal fluid in the first case in the presence of xanthochromia would seem comparable to the above findings—a meningeal reaction to remote subarachnoid bleeding caused by the same trauma that initiated the slowly growing subdural collection. The intense meningeal reaction with the resulting high spinal fluid polymorphonuclear leukocyte count that was present in the second patient is an exception to the findings of the above-mentioned workers and is an example of a case of acute subdural hematoma with unusual leukocytic reaction to associated subarachnoid bleeding. It was erroneously diagnosed as an acute bacterial meningitis because the polymorphonuclear leukocyte response was not thought to be consistent with an aseptic meningeal reaction. Both cases emphasize that the leukocyte count of the spinal fluid can be misleading if it is used to rule out a diagnosis of acute subdural hematoma.

It is generally realized that the trauma producing subdural bleeding giving rise to hematoma can be accompanied by a cortical contusion and subarachnoid bleeding. Just as the finding of bloody spinal fluid by lumbar puncture after trauma does not militate for or against an associated subdural hematoma, so also polymorphonuclear or lymphocytic cells in spinal fluid consequent to subarachnoid bleeding and meningeal irritation do not rule out subdural hematoma. A hint that the leukocytic reaction might have been due to previous subarachnoid bleeding rather than infection was afforded by the xanthochromic character of the supernatant spinal fluid when grossly bloody (case 2) or its yellow color when erythrocytes were no longer present (case 1). The absence of bacterial infection was then further established by the finding of normal spinal fluid sugar content in each instance.

SUMMARY

Two cases of subdural hematoma in which elevated spinal fluid leukocyte counts led to erroneous diagnoses of meningitis emphasize that the leukocyte count of the cerebrospinal fluid is not, by itself, diagnostic of meningitis and should not prevent exploratory trephination of the skull when a growing intracranial mass is suggested by progressive deterioration of sensorium. Because of the insidious behavior of the subdural hematoma, even a temporary misdirection in the management of such a case as probable meningitis can result in fatality, while complete recovery can be achieved by early surgical intervention.

GLUCOSE-INSULIN TOLERANCE TEST IN RHEUMATOID ARTHRITIS

STUDY OF TWENTY-NINE CASES

Jacques Houli, M.D.
and
Helion Povoa Filho, M.D., Rio de Janeiro, Brazil

There is still doubt concerning the presence of pituitary or adrenal insufficiency in patients with rheumatoid arthritis. The glucose-insulin tolerance test has previously been studied by several authors and is considered a good index of pituitary and adrenal function.[1] The test is based on the observation that, in normal individuals, the administration of glucose (30 to 60 minutes after insulin-induced hypoglycemia) is followed by hyperglycemia of greater intensity than that obtained by giving glucose without previously giving insulin.[2] Thus, administration of glucose accentuates the homeostatic reaction to hypoglycemia, believed to be mediated by hormones of the anterior pituitary and from the adrenal cortex and medulla.

Patients with adrenal or pituitary insufficiency and with hyperinsulinism show an exaggerated reaction to insulin, and spontaneous rise in the blood sugar level after induced hypoglycemia is retarded.[1a] One of the advantages of the glucose-insulin test is that, with the administration of glucose, the danger of a marked degree of hypoglycemia is avoided. It is well known that, in the presence of a marked degree of adrenal insufficiency, hypoglycemia can be fatal. Nevertheless, in suspected cases of adrenal cortical hypofunction (Addison's disease) or hypopituitary cachexia (Simmond's disease), it is advisable to use only one-half or one-third of the usual dose of insulin. This test has been analyzed in various morbid conditions and was found to be of value in the diagnosis of adrenal and pituitary insufficiency.[1a] In nine patients with prolonged malnutrition, secondary to nervous anorexia, serious organic disease, and uncontrolled vomiting (neurosis), the test was normal in seven cases, abnormal in one (nervous anorexia), and doubtful in one.[1a] Rapid and distinct rise in blood sugar level after insulin and glucose therapy is a strong argument against the presence of adrenal or pituitary insufficiency. However, there are authors who believe that the alterations of glucose metabolism are not the cause but the secondary effect of the rheumatic process.[3]

TECHNIQUES OF GLUCOSE-INSULIN TESTS

We studied the glucose-insulin tolerance test as a method of investigating the possible presence of adrenal or pituitary insufficiency in a group of 29 patients with rheumatoid arthritis. Among those, 26 patients had a good general condition and nutritional status and the remaining 3 (cases 5, 6, and 7 of group 2) did not. In the first group of 12 patients we applied the technique of Fraser and co-workers,[1b] and in the second group of 17 patients the technique used was that of Engel and Scott.[1] The previous diet of both groups was a regular one.

Technique of Fraser.—In Fraser's technique [1b] the first sample of blood is collected in the fasting state, immediately followed by the oral administration of 100 gm. of glucose and 0.1 units of regular insulin given intravenously per kilogram of body weight. Additional samples of blood are taken after 20, 30, 45, 60, and 90 minutes. About 120 minutes later, 0.01 ml. of epinephrine was injected intramuscularly, and additional samples of blood are taken after 165 and 180 minutes. By the simultaneous administration of glucose and insulin the changes in serum glucose levels normally are very slight. After the administration of epinephrine, with the intention of mobilizing hepatic glycogen, the glucose level must increase between 35 and 45 mg. per 100 cc. in 40 to 60 minutes. With this technique we studied one group of 12 patients in the various evolutive stages of rheumatoid arthritis according to Steinbrocker's criteria: 1—initial, 2—moderately advanced, 3—advanced, and 4—terminal (table 1). All the results were normal.

TABLE 1.—*Results of Glucose-Insulin Test in Twelve Patients, by the Technique of Fraser and Co-Workers*

			Serum Glucose Levels, Mg./100 Cc.							
			No. of Min. After Administration of Glucose and Insulin						No. of Min. After Administration, with Addition of Epinephrine	
Case No.	Evolutive Stage *	Fasting Blood Sugar Level, Mg./100 Cc.	20	30	45	60	90	120	165	180
1	2	95	115	110	130	130	125	120	150	145

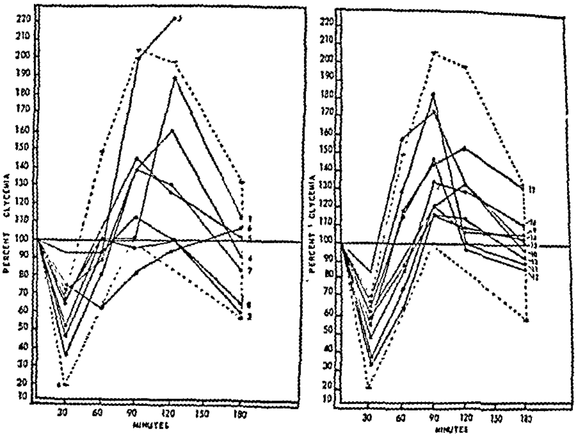
3	2	90	140	170	180	190	135	130	130	150
4	1	90	110	110	105	125	101	90	115	130
5	3	105	115	145	170	165	95	95	175	135
6	3	90	125	145	190	190	180	160	175	155
7	2	85	135	125	130	115	115	120	180	170
8	2	90	95	100	130	140	125	100	165	170
9	3	115	240	160	195	240	215	145	160	185
10	2	95	95	115	150	155	125	80	140	150
11	3	90	105	120	150	140	130	155	180	175
12	2	80	55	55	70	80	105	95	155	155

* According to Steinbrocker's criteria: 1, initial; 2, moderately advanced; 3, advanced, and 4, terminal.

Technique of Engel and Scott.—After taking one blood sample in the fasting state we injected 0.1 unit of regular insulin per kilogram of body weight. Thirty minutes after (or before, if symptoms of hypoglycemic shock appear) a new blood sample is taken, and we administer 0.8 gm. of glucose orally per kilogram. New blood samples are taken 60, 90, 120, and 180 minutes from the beginning of the test. We studied 17 patients in various stages of the disease. The results, given in milligrams, are tabulated in table 2. The figure gives the findings in percentage of the initial blood sample that was considered as 100%. The results were normal in all instances. We wish to emphasize that the two groups on whom tests were done consisted of different patients.

SUMMARY

The study of the glucose-insulin tolerance test, as a method of determining the possible presence of adrenal or pituitary insufficiency in patients with rheumatoid arthritis in the various evolutive stages of the disease, gave normal results in two groups of patients. In one group of 12 cases studies were done by the technique of Fraser and co-workers and in the other group of 17 patients by the technique of Engel and Scott.



Glucose-insulin tolerance test in 17 cases of rheumatoid arthritis in various evolutive stages, by Engel and Scott's technique. Interrupted lines give the boundaries of normality. Left, cases 1 to 8. Right, cases 9 to 17.

The material on the following pages constitutes the 55th annual report on "Medical Education in the United States and Canada," compiled by the Council on Medical Education and Hospitals. It includes data derived from official sources concerning schools of medicine and matters of information pertinent to medical education. The presentation of this information would not be possible without the full cooperation of medical school and university administrative officers, government officials, and many others. The Council on Medical Education and Hospitals wishes to express profound appreciation to the many individuals who have provided the information on which this current report is based.

Introduction

In the introduction to the comprehensive self-analysis of "Medical Schools in the United States at Mid-Century," Deitrick and Berson[1] indicate certain basic premises in their concern with the definition of a medical school and its responsibilities. These premises, involving fundamental principles in the education of a physician against which present-day medical education can be measured, are of interest and concern to all engaged in this important field of activity. Because the Council on Medical Education and Hospitals believes these principles to be of fundamental significance, they are referred to in this introductory statement for reflection and as a keynote in the study of the accompanying data on medical education.

First of all, "a medical school is held to be an educational institution concerned with a certain body of scientific and empiric knowledge, to which it should continue to make additions, and with which two individuals, the teacher and the student, must deal in order to understand and help a third person for the purpose of maintaining his health or overcoming his illness."

This necessitates the acceptance of two major responsibilities on the part of a medical school in the development of its educational program. The first of these is directed to its students and the second to society, through the individuals graduated as physicians. Because the medical school is the means of approach to a career in medicine, medical schools naturally are largely responsible for the medical profession. Because of this, the first and perhaps most important consideration of those vested with responsibility "is that the students must be the best human material that the faculty can select."

It is axiomatic that the medical student is the central factor in medical education and that all basic policies and activities be planned and conducted so as to create the best possible environmental circumstances and opportunities for him. The student entering upon the study of medicine has been molded by 20 years or so of development and education, and many of his acquired faults and weaknesses cannot be readily corrected by four years of medical education. The student's attitude and point of view and the level at which the medical school can initiate its educational program effectively are determined to a large extent by the type and quality of the preprofessional education he has experienced. Thus preprofessional education has become of increasing importance to medical educators and deserving of greater attention on their part in the continuing study of the background for medical education.

Data in table 20 are derived from table 2 of Stalnaker, J. M., and Dykman, R. A.: The Study of Applicants, Association of American Medical Colleges, to be published, and appears with permission of the authors.

[1] Deitrick, J. E., and Berson, R. C.: Medical Schools in the United States at Mid-Century, New York, McGraw-Hill Book Company, Inc., 1953.

In the educational program in the medical school, there is no question but that the caliber of the faculty personnel and their attitude, sincerity of purpose, and interest in education are of greater importance than the exact manner of curriculum organization. The basic function of teaching and instructional methods, in addition to the acquisition of knowledge, lies in its potentiality to stimulate students to develop their own latent capacities and interests. Opportunities and experiences designed to stimulate the development of these student potentials should, therefore, be offered the student during his medical school exposure. Individuals entering the field of medicine today must develop a sound concept of the experimental method. They must develop an understanding of the principles and methods of the basic sciences so essential to comprehension of clinical medicine. During the undergraduate medical school experience, students must become familiar with sound methods of patient study under careful and critical supervision. It is imperative that those who teach in schools of medicine should be individuals who in their daily work, through precept and example, represent the highest concepts of ethics and professional care. This should begin with the very first contacts in medical school and must be fully as applicable in the basic medical sciences as in the undergraduate clinical fields of study and consistently encountered later through every phase of graduate and postgraduate medical education.

As far as the curriculum is concerned, it will be fully effective only if carefully designed for the benefit of the student and based on sound educational principles. A good curriculum is one that has been cooperatively designed by the faculty, which in turn is fully aware of the objectives and responsibilities of the institution. Such a curriculum will always be developed with the student as the key figure, incorporating the perspective and balance essential to attaining the objectives desired. A good curriculum cannot exist when there is lack of faculty understanding of program objectives or where there is a dearth of intercommunication and participation in its development.

By the time a student has completed his undergraduate medical program, he should possess a reasonable understanding of science, man, his health, diseases, and disabilities. He should have developed a genuine spirit of curiosity and be in possession of methods of study which foster the accumulation of facts and the making of observations that lead to new knowledge and the wisdom to utilize it. This should be only a healthy beginning, for, as Sherlock Holmes is supposed to have commented, "Like all other arts, the science of deduction and analysis is one that can only be acquired by long and patient study, nor is life long enough to allow any mortal to attain the highest possible perfections in it." However, during this period of study the medical student should have, as Deitrick and Berson state,[1] "experienced the satisfaction of facing, studying, understanding, and mastering by himself problems of science or of a patient's illness." If this has been the case, the foundation will be secure, basic medical education will have served its purpose, and the young physician will continue to gain the satisfactions emanating from continuous study, and constantly increasing knowledge and understanding.

It is important that medical education aid in developing competence, not only in individual endeavor but also in the concept of effective cooperation and teamwork. The tremendous advances of knowledge in the field o science and their application to medicine in recent year have augmented the necessity of cooperative teamwor as well as continuous education. The more firm th knowledge of basic sciences, the broader the factua information possessed, and the more intelligently phy sicians organize their knowledge, the greater the scientific service they can render their patients. In additio however, every physician who deals with people mus possess a genuine understanding of human beings an a sympathy for those aspects of medicine which transcend pure science. Here is where nothing can replac "precept and example" on the part of medical teache and other members of the medical profession in helpin to mold the student and young professional into the pa tern of the true physician who can serve his fellow me best in their over-all needs.

As each school continuously reevaluates its own pr gram, there is opportunity to determine how closely comes to fulfilling the definition and function of a med cal school as indicated by this midcentury concept.

Interesting and stimulating developments are co stantly taking place in the field of medical education. retrospect, the impression cannot be avoided that th increased interest in self-evaluation of curriculum techniques, and methodology has been given gre impetus as a result of the improved intercommunic tion of recent years. Undoubtedly, the increasing valu of medical and other scientific society meetings durin recent years has played an important role. Howeve the events that seem to have made the greatest in mediate impact on the administrative officers and facu ties of medical schools began with the Conference o Psychiatric Education[2] in 1951 held under the sponso ship of the American Psychiatric Association and th Association of American Medical Colleges. This stimulating and successful conference was followed by on on preventive medicine in medical schools[3] held a Colorado Springs in 1952 and cosponsored by th Conference of Professors of Preventive Medicine an the Association of American Medical Colleges. Thes conferences were made possible through generous support from organizations such as the Rockefeller Foundation, the Commonwealth Fund, the National Foundatio for Infantile Paralysis, the John and Mary R. Markl Foundation, the National Tuberculosis Association, th Metropolitan Life Insurance Company, the Albert an Mary Lasker Foundation, the W. K. Kellogg Foundation, and the United States Public Health Service. Medical education owes these private and public agencie sincere appreciation for the encouragement, assistance and support given during recent years that have made possible these valuable conferences and institutes.

---

[2] Psychiatry and Medical Education: Report of the 1951 Conference on Psychiatric Education Held at Cornell University, Washington, D. C., American Psychiatric Association, 1952.

[3] Preventive Medicine in Medical Schools: Report of Colorado Springs Conference: November 1952, J. M. Educ. 28: 1-123 (Oct., pt. 2) 1953.

These two background conferences were carefully planned to evaluate and compare what was being done by the various medical schools and to develop suggestions for improving methods of education in these areas. Those who attended these conferences carried their reactions over to the group attending the subsequent meetings of the Association of American Medical Colleges, as well as directly back to their respective faculty groups. The stimulating success of these initial conferences has been followed by the first two of a series of six annual teaching institutes that have been conducted by the Association of American Medical Colleges. The first of these was held at Atlantic City, N. J., in October, 1953, and covered the area of physiology, biochemistry, and pharmacology.[4] In October of 1954, the teaching institute covering the area of pathology, microbiology, immunology, and genetics was held at French Lick Springs, Ind.[5] The 1955 teaching institute to be held preceding the Association of American Medical Colleges meeting in October will cover the fields of anatomy, histology, embryology, and anthropology. Currently, the schedule calls for a 1956 teaching institute on medical ecology, 1957 teaching institute on clinical teaching, including the internship, and one on specialty training and the continuing education of the physician in 1958. It is to be anticipated that these institutes will continue to stimulate further and continuous curriculum modification, as well as enhance the effective utilization of successful educational experimentation, methods, and technics.

At the annual Congress on Medical Education and Licensure in February, 1955,[6] the Council on Medical Education and Hospitals conducted for the first time a full day conference dealing with a specific area of interest in postgraduate medical education. This conference was centered around "The Potential Use of Television in Postgraduate Medical Education." The morning session of the regular Council program dealt with a symposium on "Legal Medicine in Undergraduate Medical Education" and the afternoon session with a symposium on "The Future of the Internship."

In cooperation with the Federation of State Medical Boards of the United States, the Association of American Medical Colleges, and the American Hospital Association, the Council has been endeavoring to aid in the development of a more satisfactory means of evaluation of graduates of foreign medical schools. Numerous meetings have been conducted to date and suggested basic policies outlined. Currently, the study is still in progress. It is hoped that further progress toward a satisfactory solution to this problem will be continued during the years ahead, as the lack of such solution has significant potential impact on both medical education and licensure in this country and should be solved in the interest of public welfare and service.

The completion of the survey of postgraduate medical education in the United States and the publication of the series of articles in THE JOURNAL [7] covering its various aspects should be of interest to medical educators. This report indicates that medical school faculties are undoubtedly destined to play a role of increasing importance in this area of continuing medical education as time goes on. Medical schools might well be advised to take a careful look at their own past efforts in this area of medical education. It is important for medical educators to study and analyze such matters as the objectives and content, the best educational methods to utilize in this field, the most desirable time and place arrangements, sponsorship, financing, and challenges of postgraduate medical education. Its further development must be sound and rewarding to all who seek it. Its development must not interfere with, but should enhance, undergraduate medical education and research. Continuing medical education will need the careful thinking of medical educators and of the medical profession in cooperative planning towards the attainment of maximum value from time and effort invested on the part of both groups.

Medical Schools

APPROVED MEDICAL SCHOOLS

During 1954-1955, the University of California at Los Angeles completed the initial development of its four year undergraduate program in medicine and was granted full approval by the Council on Medical Education and Hospitals. It has also become a member of the Association of American Medical Colleges. There are now 75 approved four year schools of medicine and six approved schools of basic medical sciences, for a total of 81 approved institutions in the United States (table 1). Currently there are 11 approved four year medical schools and one approved school of basic medical science in Canada (table 2).

This year these tables on approved medical schools and schools of the basic medical sciences in the United States and in Canada have been modified and enlarged so as to include more summary data on each medical school. This has obviated the need for the annual reduplication of the short historical summary of the schools heretofore included at the end of the report. The current data includes the name of the school, its location, ownership, year of organization, current tuition, dates of next academic year, premedical years of study required, number of students by class, part-time and special students, number of graduates, and the executive officer of the institution. Data for the Canadian schools also includes the enrollment of students in the first and second premedical years, those in the fifth medical year, as well as those in a required intern year where indicated.

* During the year of this report, the University of Miami School of Medicine, Coral Gables, Fla., had only the first three classes in attendance. Since medical schools are not eligible for full Council approval until all four years are in operation, students enrolled at Miami in 1954-1955 (first year class—69, second year—36, third year—26, total—131) are not included in this and following tables.

† S = state, P = private, M = municipal.

‡ Data for total enrollment in previous years in table 11 include only full-time students.

§ Two classes.

Table 3 summarizes the development and growth of approved medical schools in the United States during the period 1910-1955. It clearly portrays the growth from 66 approved schools graduating 3,165 physicians in 1910 to the present 81 graduating 6,977 in the spring of 1955. The growth of student enrollment in approved schools from 12,530 in 1910 to 28,583 in 1955 has been in keeping with the population growth of the nation during this period and indicates, furthermore, that not only have new schools developed but many older institutions have augmented their facilities so as to educate larger numbers of students as the demand has arisen.

According to classification by ownership, there are now in the United States 41 privately owned, 37 state, and 3 municipal medical schools (table 1).

The relatively rapid turnover of medical school administrative personnel that has occurred during recent years continued during 1954-1955 with the appointment or pending appointment of new executive officers in 11 approved medical schools in the United States. Ten such changes were made in 1953-1954. Institutions which made new administrative personnel adjustments in 1954-1955 include the University of Arkansas, College of Medical Evangelists, Howard University, Chicago Medical School, the University of Maryland, Boston University, New York University, Hahnemann Medical College, University of Texas (Galveston Branch), the University of Utah, and the University of Wisconsin.

NEWLY DEVELOPING MEDICAL SCHOOLS

Table 4 lists the four completely new four year medical schools and the three formerly two year basic medical science schools extending their programs to four year curriculums, that are currently in various stages of development. The table indicates whether a program is entirely new or extended and lists the estimated year of graduation of its first class of physicians. By 1960, therefore, there should be 82 four year medical schools and 3 two year schools of the basic medical sciences in the United States, if these currently developing programs are completed on schedule.

At the University of Miami School of Medicine the outpatient clinic building has been constructed on the grounds of the Jackson Memorial Hospital. It was scheduled for occupancy and activities in June, 1955, and will be the location of the major portion of the fourth year teaching program. Architectural working plans for the basic science building to be erected at the Jackson Memorial Hospital site have been completed. In the meantime, basic science teaching and research activities continue in the building occupied in Coral Gables. Further faculty and curriculum developments have taken place, and the first class is scheduled to complete the undergraduate medical course in June, 1956. A liaison survey visit will be conducted during November, as the school enters its full four year program.

The University of Mississippi School of Medicine has completed its 9 million dollar construction. Faculty development and curriculum planning for the clinical years are well along. As has been the experience in relation to other developmental programs in some of the medical schools of state universities, difficulties have arisen in connection with the establishment of policies regarding employment of clinical faculty personnel. It is to be hoped that this problem has been adjusted on the local level to the mutual satisfaction of the university, the school of medicine, and the medical profession.

At the University of Missouri, all of the primary construction planned for its four year medical school is under way. The 450-bed teaching hospital and outpatient departments are close to completion. Major structural elements of the new Medical Sciences Building are in place, and the building is scheduled for occupancy at the end of the 1955-1956 academic year. Construction is also progressing on the new nursing home. Staffing of the new medical school's faculty is well advanced. The third year curriculum has been established, and the first third year class will initiate its studies in September, 1955, with the first group of candidates for degrees scheduled for graduation in June, 1957.

Construction on the $10,695,000 Basic Sciences Building at the West Virginia University School of Medi-

cine has been initiated. At the time of this report, the basic steel construction has been completed.

The Albert Einstein College of Medicine of Yeshiva University is far advanced in its faculty organization and construction program. The new Nathan B. Van Etten and Abraham Jacobi Hospital units are completed and in operation. The first unit of the medical college building under construction adjacent to the hospital site is nearing completion and will be ready for occupancy late in the summer of 1955. The basic curriculum planning has been completed, and the first class has been selected to initiate its studies during the academic year 1955-1956.

Seton Hall College of Medicine is now being developed at the Jersey City Medical Center. The university has consummated a 50 year contract with the city administration that permits the new schools of medicine and dentistry to occupy the 16 story former outpatient building of the Jersey City Medical Center. This building is being remodeled to meet the needs of the two new professional schools for teaching, research, library, and certain clinic accommodations. Under the current agreement the city rents this building to the university and a mutually satisfactory program of maintenance has been consummated. At the present time, faculty organization, curriculum planning, and reconstruction activities are under way. It is anticipated that the program development will make it possible to graduate the first class of physicians in 1960.

The developmental program at the University of Florida School of Medicine at Gainesville is well under way. Building construction has been initiated for the Medical Sciences Building which will include both basic science and clinical wings, library, and auditorium. The completed center will include a hospital unit of about 350 beds for patients with acute conditions, an ambulant patient facility with 50 beds, and clinic facilities. Faculty organization and further curriculum planning are currently being developed. It is anticipated that the first class of students will be candidates for degrees in the spring of 1960.

In last year's Education Number of THE JOURNAL it was reported that the University of Kentucky's board of trustees had formally sanctioned the establishment of a medical school in Lexington and that funds were to be sought from the Kentucky General Assembly. The Kentucky Medical Sciences Development Foundation was created to promote interest in the project and to receive funds from private sources as well as to file articles of incorporation and formulate building plans tentatively for July 1, 1955. At the present time, the foundation is conducting a program of public information as to the medical needs within the state. It was also reported last year that the North Dakota legislature had directed its School of Medicine to admit a third year class by 1955 and that a full four year program be in operation by 1956. Currently this development is being held in abeyance.

There has been consideration of the possibility of the development of a medical school at Hartford, Conn., as a unit of the University of Connecticut. In 1953 a commission was authorized by the state legislature to study the feasibility of such a development. Subsequently the commission reported favorably on the project and also recommended that the state of Connecticut participate in the New England Regional Compact for Higher Education, including medicine. The commission recom-

TABLE 3.—*Schools, Students, and Graduates in Medicine, 1910-1955*

mended that the trustees of the University of Connecticut be directed to proceed forthwith in the development of the medical school and asked for a special bond issue of 6 million dollars for primary financing. Later study resulted in the introduction of a substitute measure directing the appointment of a new commission, including members of the board of trustees of the University of Connecticut, to proceed with preliminary planning for a medical school, site determination, and appropriation of $50,000 for initial costs. Since the recent Connecticut legislature adjourned prior to consideration of this bill, no further action will take place until the next biennium unless a special session shall be called.

A year ago, some consideration was being given to the establishment of a medical school in Toledo, Ohio. At the present time there is no indication that such a development may occur in the immediate future.

The Massachusetts House has rejected legislation calling for the establishment of medical and dental schools at the University of Massachusetts. Massachusetts has joined in a five state pact which may eventually evolve into the establishment of a regional medical school.

TABLE 4.—*Medical Schools Currently Developing Four Year Programs*

Seton Hall College of Medicine and Dentistry..	Completely new school	1960
University of Florida School of Medicine.......	Completely new school	1960

From various quarters there is constant representation of increased needs for medical personnel. Needs for additional facilities for the education of physicians are exceedingly difficult to determine and require careful analysis of who represents what need. No one will deny the fact that, with a constantly growing population and with the ever-increasing health consciousness of the nation, there will be a constant and continuous demand for increased numbers of medical personnel and that this will necessitate new medical schools and possible augmentation of the facilities and faculty personnel of those now in existence. The many areas such as medical administration, teaching, research, military services, veterans administration, and public health services unquestionably remove many physicians from active private medical practice today. On the other hand, there are now large numbers of personnel trained and employed in ancillary fields supporting and assisting in certain aspects of diagnosis and medical care under medical supervision. Needs are presented and interpreted differently by different groups. Some indicate needs primarily in terms of distribution of personnel, others in terms of the type of training, experience, or service considered to be desirable, while others simply echo the idea of need with no indication of just what the need is except for vague concepts.

Increased knowledge and its utilization with the associated rapid expansion of specialization accompanied by demands for personnel in these fields have materially changed the over-all practice of medicine in recent years. Social readjustments are also making their impact on the practice of medicine. These readjustments have been relatively abrupt, and neither the general public nor the profession have become fully adjusted to them. The estimates of need for medical personnel have been reported in such studies as America's Resources of Specialized Talent,[8] which constitutes the Report of the Commission on Human Resources and Advanced Training. The figures on needs in medicine in this report are largely drawn from the report of the President's Commission on the Health Needs of the Nation[9] and the Health Manpower Source Book, Section I, issued by the Federal Security Agency.[10] Probably no analytical reports of estimated requirements that have been developed in this rapidly changing scene can accurately represent more than the existence of felt needs in some areas.

It appears, therefore, that one of the constant challenges confronting medical educators and all those interested in and concerned with medical teaching, research, and the provision of adequate medical care involves efforts to evaluate effectively current and projected needs for personnel in this field and the facilities, faculty personnel, and financing essential to their development. The new medical schools currently undergoing development will aid in meeting increasing needs for medical personnel in the years immediately ahead. What adjustments are needed, either in augmentation of student capacity of existing medical schools or in the development of new medical schools during the next quarter of a century? It is apparent that anything in the way of a reasonable forecast for even 10 years ahead involves a constant study and analysis of the whole social structure of the nation today in an effort to meet the needs for personnel in the varied and increasingly complex period that confronts it. The number of professionally trained personnel desirable in any area of human endeavor is not as simple as a ratio of such personnel per unit of population. It is far more dependent on the existing knowledge in any given area and the application of such knowledge to human activity in all phases. The field of medicine, because of its important role in human welfare and happiness and its direct implications in all other areas of activity, will continue to present demands for personnel augmentation in keeping with population growth and other factors. With the financing of medical education as difficult and precarious as it has been in recent years, it is of paramount impor-

tance that continued effort be made to stabilize more effectively existing programs and to aid in clearly forecasting the implications in terms of facilities, faculty, and financing of any new programs which may develop.

DEVELOPMENTS OF INTEREST IN MEDICAL SCHOOLS, 1954-1955

In their annual reports to the Council, many of the medical schools indicate major developments in one or several aspects of their programs. These involve changes in curriculum, altered or new approaches to certain aspects of undergraduate or graduate medical education, and readjustments in financing. There continues to be deep interest in curriculum modifications in keeping with the changing emphases on various aspects of medical education. The following material has been selected from the annual reports as illustrative of the continued dynamic thinking and action generally apparent in medical schools throughout the nation.

At the Stanford University School of Medicine, curriculum studies are being conducted in relation to the ultimate transfer of the clinical years of study from the San Francisco site to the Stanford campus. A trial run has been made at integrating courses of the second year in the spring quarter of 1954-1955 and continuing the plan for the next year. Similar basic planning is being conducted at the Indiana University School of Medicine and at the University of California (Berkeley-San Francisco) in view of the impending transfers of their first year programs to the main medical school campuses. On completion of the plans currently under way in these three schools, they will each have opportunity for the development of maximum cooperation and integration between basic medical sciences and the clinical areas which have been difficult to achieve with divided medical campuses.

On Oct. 1, 1954, the School of Medicine of the University of Miami assumed control of the professional and instructional activities of the Jackson Memorial Hospital in accord with earlier agreements made by the University, the Dade County Commissioners, and the Dade County Medical Society. A medical board has been established with representation from the faculty, the hospital administration, and the courtesy staff with the dean of the School of Medicine as its chairman.

The third and fourth year curriculums of the Medical College of Georgia has been reorganized on the "block" system. In the third year, medicine and surgery have each been allocated 12 weeks, with obstetrics-gynecology and pediatrics each being assigned 6 weeks. In the fourth year, medicine is assigned 12 weeks, of which 6 weeks will be spent in domiciliary medicine, with surgery, obstetrics-gynecology, pediatrics, and electives each having a 6 weeks' assignment. Faculty reorganization on a strict full-time basis has been initiated.

Emory University School of Medicine reports that an anonymous gift to the university has been made to underwrite the minimum budget of the institution and to stabilize its basic financing. At Emory, the division of basic sciences in the health services is now responsible for instruction in the schools of medicine, dentistry, nursing, and pharmacy, as well as in the graduate school of the university. This division is administered with an understanding of its full responsibilities to students and faculties in each of these fields, and close administrative and functional liaison is maintained with them. There are now 25 members of the clinical faculty in the partnership arrangements associated with the development of the Emory University clinic. The university believes that this clinic program as it is now developing will enhance teaching, research, and service, as well as certain aspects of financing.

At the Indiana University School of Medicine, as previously indicated, studies are being made on the integration of teaching in the basic science departments in anticipation of the transfer of the first year of instruction from Bloomington to the Indianapolis campus. Greater emphasis is being given also to improved opportunities for graduate education as new facilities are made available.

A "Senior Day" under sponsorship of the Kentucky State Medical Association was inaugurated at the University of Louisville School of Medicine on April 18, 1955. The trustees of the university have authorized the expansion of the first year class from 100 to 124 students, limiting the additional places to Kentucky residents if a sufficient number qualify.

Curriculum changes now under way at the University of Maryland will place all anatomy in the first semester of the first year. Correlation between departments is being promoted. Augmentation of financial support has provided for salary increases in the basic sciences and some adjustments in the clinical area. Provision has been made for the engagement of additional full-time and part-time faculty personnel.

Boston University School of Medicine has reorganized the third year curriculum to provide for a decrease in the number of hours devoted to lectures and increased time in the clinics, allowing more free time for elective work and establishing an improved examination schedule. The teaching of physical medicine has been incorporated into the third year program.

At Tufts College Medical School, the general medical, pediatric, psychiatric, and children's psychiatric clinics are cooperating in an effort to provide students with a realistic experience in ambulatory medicine and home care. The program is designed to permit continuity of observation of patients. The student will see a patient, adult or child, for the first time in the home and send him to the "office" (student assigned area) in the Boston dispensary if further study or follow-up is indicated or follow a patient from the "office" to the home. The same instructors will supervise the student's work both in the outpatient department and on the home service. The faculty believes that a two month period should permit the student to follow an acute illness from onset to recovery and to obtain a fair appreciation of the course and problems of chronic illness. On his "office" days the student will also actually work with any of his patients referred to the Rehabilitation Institute of the New England Medical Center. If hospitalization is required, the student will follow his patient to the ward. The objective of the program is to provide a basic orientation for family practice.

During the past year, physical diagnosis at the Creighton University School of Medicine has been taught as an interdepartmental project in the second year. The course is now designated as "Clinical Diagnosis." Some aspects of histology formerly taught in the department of anatomy have been integrated into the course in pathology. Material reduction of didactic assignments in the third and fourth years have facilitated the establishment of more effective clinical clerkships.

Albany Medical College reports continuation study by the committee charged to survey and plan for curriculum improvements. Although no major alterations have been recommended to date, there has been a reduction of departmental lectures in favor of interdepartmental "panel" instruction with emphasis on more active student participation. This has been associated with greater inclusion of basic science faculty members as participants in the panels. A series of applied basic science clinics has been introduced into the first year curriculum and is reported to have been enthusiastically received by both students and staff. Albany Medical College has taken increased interest in the field of continuing medical education. During the 1954-1955 period, the postgraduate medical education program was expanded and well received. New approaches to postgraduate medical teaching are currently being developed.

TABLE 5.—*Cost of Completed and Estimated Cost of Initiated Construction and Equipment in Medical Schools, 1954-1955*

	Schools in United States				Schools in Canada	
Purpose	No. Completed	Cost	No. Initiated	Cost	No. Initiated	Cost
Basic medical sciences teaching and research..	15	$46,981,000	15	$60,330,029	2	$2,100,000
Hospital and clinic teaching and research..	13	47,957,000	6	19,395,000	1	1,500,000
Dormitory	3	4,446,986	1	1,246,259	..	....
Totals		$99,384,986		$80,971,288		$3,600,000

The State University of New York College of Medicine at Syracuse reports the establishment of a student honor system during 1954-1955. Student participation on some faculty committees has been developed.

At the University of Oklahoma School of Medicine, a nucleus of full-time psychiatrists has been appointed to develop the teaching program in this field. Cooperatively the departments of anatomy, medicine, psychiatry, and pediatrics have developed a first year course in normal growth and development. A department of physical medicine has been developed under full-time leadership and a school of physical therapy established. Industrial medicine now is organized and taught by a full-time member of the staff of the department of preventive medicine.

Additional support from the M. D. Anderson Foundation has made it possible for the Baylor University College of Medicine to develop an enlarged program in psychiatry at both undergraduate and residency training levels. A program of research with emphasis on the pharmacological aspects of mental disorder has been initiated. An effort is being made to coordinate community facilities in the field of mental disorders. During the past year advances have been made in the over-all integration of the Texas Medical Center, of which th
Baylor University College of Medicine is a part.

The University of Vermont College of Medicine re
ports increased financing of its program through sta
sources. The curriculum of the second and fourth yea
has been drastically modified to allow correlation in th
second year of all courses with the course in patholo
and to allow extensive work in the outpatient departme
during the fourth year.

Queen's University Faculty of Medicine has separat
its department of eye, ear, nose, and throat into depa
ments of ophthalmology and otorhinolaryngology.

The University of Saskatchewan College of Medici
will initiate its first third year of instruction in the f
of 1955. The departments of medicine, surgery, pe
atrics, psychiatry, social medicine, and rehabilitati
will continue efforts to present integrated instruct
in lectures and correlation clinics. McGill Univers
Faculty of Medicine reports the appointment of a co
mittee to reevaluate its over-all curriculum and obj
tives and to recommend such modification as deem
desirable.

CONSTRUCTION OF FACILITIES

The annual reports from the medical schools to
Council indicate that during 1954-1955, 35 instituti
in the United States and 2 in Canada have either co
pleted or initiated construction and equipment of
facilities. Table 5 summarizes this information. C
pleted construction in medical schools in the Un
States totaled $99,384,986 of which $46,981,000
for basic medical sciences teaching and research, $4
957,000 for hospital and clinic developments,
$4,446,986 for dormitory facilities. Construction
tiated totaled $80,971,288, of which $60,330,02
for basic medical sciences teaching and research, $1
395,000 for hospital and clinic programs, and $1,2
259 for dormitory facilities. Two Canadian schools
port the initiation of construction estimated to
$2,100,000 for basic medical sciences, and one rep
$1,500,000 for initiated clinical laboratory facilities

The significance of these figures is definitely limit
They indicate that considerable sums are being
pended to improve and augment facilities for med
education. They do not, however, give a clear or co
prehensive picture of developments of hospital and cli
facilities that are utilized as part of medical educat
programs but financed by governmental or private fu
and not by the school. Such developments as the
Metropolitan, Jacobi, and Van Etten hospitals in N
York City, which will become the major basic clini
teaching units of the New York Medical College a
Albert Einstein Medical School in return for the p
fessional care responsibilities assumed by the medi
schools, represent tremendous investments of significan
to medical education although their chargeable value
it would be impossible to determine with any reasona
certainty. Grady Hospital in Atlanta, in which some
the clinical teaching of Emory University Medical Scho
is conducted, is another example among many whe
professional responsibilities for patient care are assum
by the school in return for the educational advantag
afforded by the hospital. The many examples of arrang

ments of this and similar types make it almost impossible to give an accurate picture of the investments in facilities and equipment that in some way have impact on opportunities in medical education.

REGIONAL PROGRAMS AND MEDICAL EDUCATION

Because of the relatively high cost of medical education, it is important that existing facilities in this field be used to their maximum potentialities and that their support be reasonably distributed. In the past some of the states unable to finance the development of higher education in its various branches lacked opportunities for some of their students. State-supported institutions have tended to restrict admission to outside students partially because of the fact that tuition represented such a small factor toward coverage of actual educational costs. During recent years the development of cooperation among groups of states through the mechanism of regional compacts in higher education has indicated one of the ways financing can be improved and costs more reasonably equalized per student among compact states. Both private and public institutions have been utilized in the interstate compacts to date, and it is important that both continue to participate in any future developments of this nature.

Because of the potential significance of broader opportunities in professional education and its improved financing through the medium of interstate cooperation, it is felt desirable to present a résumé of developments along these lines in the current report on medical education. The important implications of cooperative programs of this type transcend the field of undergraduate medical education and may in the future have increasing significance in continuing education through regional postgraduate medical education programs.

Several years ago 14 southern states approved a compact under which they obligated themselves to work with each other, with colleges and universities, and with agencies concerned with higher education to the end that through joint effort they might more rapidly advance knowledge and improve the social and economic level of their region. In the fall of 1948, a full-time staff was set up to survey the most urgent needs of the region in the field of professional and graduate education. Commissions were appointed on medical and related training (including medicine, dentistry, nursing, and pharmacy), veterinary medical training, and graduate studies, and careful evaluations were made by them.

The first regional activity which was undertaken by the Southern Regional Education Board (1949) was based on the exchange of funds between states desiring training for students in certain professional fields in which those states themselves did not provide student facilities and institutions which could provide them. To make this possible, contracts were established between the board and the states on one hand, and between the board and the institutions on the other. During 1951-1952 contracts in medicine, dentistry, veterinary medicine, and social work provided places for approximately 850 students. In 1952-1953, the program provided places for 1,059, and since that time it has continued to grow and to serve an effective role.

During 1954-1955, a total of 1,004 "regional students" were enrolled in 18 institutions under the Southern Regional Education Board. Their home states paid an aggregate of $1,314,715 to the institutions they attended. The third group of "regional students" have received their professional degrees in medicine (84), dentistry (69), veterinary medicine (96), and social work (16). With the graduation of this group, nearly 700 southern students have completed such professional training as a result of the Southern Regional Education Board contract arrangements.

The Southern Regional Education Compact and its bylaws indicate two general means by which the Regional Education Program may be developed. One of these is the joining of existing institutions and agencies in planning and executing regional programs in education; to date, this is the method that has been utilized. Secondly, provision is made for the establishment of new institutions to meet the region's needs, but only if existing institutions do not have adequate facilities and do not wish to create them.

In 1949, governors of 11 western states and 2 territories unanimously endorsed the principle of close interstate cooperation in higher education. The Western Governors' Conference concluded that not all states individually had sufficient numbers of potential students to warrant the establishment and maintenance af adequate facilities in all the essential fields of technical, professional, and graduate training; nor did all the states have the financial ability to furnish within their borders institutions capable of providing acceptable standards of training in all these fields. They did, however, express the conviction that some of the western states or groups of them could provide acceptable and efficient educational facilities to meet the needs of the region and its students. It is of interest to comment that, prior to the endorsement of the regional principle by the Western Governors' Conference, the University of Colorado School of Medicine had established a program whereby students from a neighboring state were accepted under provisions that the sender state transfer funds to cover basic educational cost above tuition. Even earlier the Medical College of Virginia and Meharry Medical College had developed programs involving interstate cooperation and financing.

By March of 1955, nine of the western states had ratified the Western Interstate Compact for Higher Education. An idea of the manner in which the program works can be presented by the example of the state of Washington, which was the ninth state whose legislature ratified the compact last March. Along with enabling legislation the state legislature passed an appropriation to share the costs of operating the Interstate Commission for Higher Education. About one-third of the students in Washington's professional school of veterinary medicine at the state college and from 10 to 15% of those in medicine and dentistry at the university have been coming from other states that are now members of this compact. Washington's membership now provides an opportunity for other compact states to send students to Washington's professional schools under the contract program. For each of these students in the program, Washington will be able to collect not only regular in-state tuition but also special fees (paid by the sending state) of $2,000 for medicine, $1,600 for dentistry and $1,200 for veterinary medicine. The legislation which was approved "cedes none of the rights of the institutions nor of the state." It is permissive only and permits arrangements by which states sending students tangibly help meet educational costs of their education in an institution supported by another compact state.

During recent years various groups in New England have discussed proposals for the establishment of some form of cooperative machinery for higher education. In May of 1953 the legislatures of Maine, New Hampshire, and Vermont authorized their state universities to act as agents for entering into contracts with institutions in or out of the state, private or public, to supply medical and dental education or any education not offered at the home state university. This enabling legislation was the first step toward greater regional cooperation in the New England area. There currently is considerable interest in a five or six state regional arrangement in New England. Whether in medicine this will be restricted to improve support for existing schools or ultimately bring about the establishment of a new school under the sponsorship of several states has not yet been determined.

TABLE 6.—*Estimated Sources of Basic Medical School Operating Budgets, 1955-1956*

No. of Schools	Source of Funds	Amount	Percentage of Total
48	Government (state, municipal, federal) appropriations	$47,727,835	48.7
47	Endowment income	10,358,181	10.6
81	Tuition income	19,210,304	19.2
34	General university funds	6,286,416	6.3
78	Gifts, grants, and other sources	14,429,885	15.2
	Total	$98,012,621	100.0

MEDICAL SCHOOL FINANCING AND ESTIMATED 1955-1956 BUDGETS

In keeping with the annual reports of the past several years, the Council on Medical Education and Hospitals has endeavored to present statistical information in regard to the financial support of undergraduate medical education and certain allied activities. The questionnaire on Medical School Statistics for 1954-1955 included an inquiry on projected budgetary information for 1955-1956. The following information was requested: (1) anticipated income and its source for general operating expenses of the medical school exclusive of income for hospitals, grants for research, and special projects, (2) anticipated income from outside agencies for research projects and teaching grants, (3) anticipated income available for hospitals or dispensaries owned by the medical school, and (4) a provisional breakdown of approximate allocations of the budget to administration, maintenance of buildings and grounds, equipment and supplies, salaries, research supported directly by the school, and other expenses.

As has been previously reported, there are many variables involved in medical school financing, and it is difficult to ascertain that all institutions have presented data so that it can be uniformly interpreted. The complex nature of teaching programs tied in with medical service activities, certain aspects of research, and educational services rendered to other schools or hospitals within the fabric of a university organization all make it exceedingly difficult for some institutions to evaluate all budget factors with certainty. True comparative analysis of medical school budgets is difficult because of the great variations in institutional organization and responsibilities. The accompanying data is restricted, therefore, to a presentation of general information in regard to current medical school financing based on material submitted to the Council in response to the present medical school questionnaire.

For purposes of this report the term "basic budget" is restricted to funds utilized for the operating activities of the school exclusive of appropriations for hospitals and clinic operation and maintenance or grants-in-aid for research or teaching from outside sources. Estimated 1955-1956 basic budgets for the 75 four year schools in the United States total $95,458,428 and for the 6 two year schools of basic medical science, $2,554,193. Thus, the total anticipated 1955-1956 basic budget for the 81 approved medical schools in the United States is $98,012,621. Forty-two of the four year and five of the two year schools receive governmental appropriations from state or municipal sources, and one four year school obtains federal funds for its basic budget. Such governmental appropriations account for $47,727,835 (48.7%) of the total projected 1955-1956 basic budget for medical education. Forty-six of the four year and one of the two year schools report $10,358,181 (10.6%) of the total basic budget as anticipated from income on endowment. Tuition charges in the 81 medical schools for 1955-1956 will approximate $19,210,304 (19.2%) of the total. Thirty-four schools indicate that $6,286,416 (6.3%) of the total basic budget will be derived from general university funds. The remaining $14,429,885 (15.2%) will be derived from gifts, grants, and other sources.

This analysis is presented in summary form in table 6. It is desirable to emphasize that this summarization constitutes a general picture of the source of total funds in each of the categories in relation to the total projected 1955-1956 basic medical school budget. The percentage allocations, therefore, should not be interpreted as the budget distribution of individual schools. For instance, 33 of the 81 schools receive no basic budget appropriations from governmental sources, 34 have no endowment income, and only 33 report allocations from general university funds. On the other hand, in some state institutions governmental appropriations constitute the major source of all basic budget funds, while in some private schools the largest single source of anticipated income is endowments. It is relatively easy to determine the total estimated income from tuition and the percentage of the anticipated basic budget which it represents for all institutions. However, the importance of the tuition income factor in the budgets of individual schools varies widely from less than 2% in one of the state-supported schools to over 84% in one of the private institutions.

The projected 1955-1956 basic budget represents an increase of $4,604,309 over the 1954-1955 anticipated budget presented in the last report. Since this 1955-1956 budget includes one new four year school budget and materially augmented budgets in two of the schools currently enlarging their programs from two to four year institutions, the actual over-all increase for the remaining 78 approved schools represents less than 2 million dollars. Thus, in interpreting data from year to year, it is necessary to know whether any increase over a previous year represents the same number of medical schools or whether it includes additional medical school budgets or augmented budgets of two year schools enlarging to four year programs.

There is a marked increase in anticipated estimates of support from research grants from outside agencies. The sum of $54,470,989 projected for 1955-1956 represents an increase of $9,087,115 over the amount anticipated from such sources in 1954-1955 Teaching grants from outside agencies to medical schools during 1955-1956 are estimated at $7,035,905, an increase of only $161,494 over the previous year. Thus, in funds obtained from sources for activities supported in addition to those covered by the basic medical school budgets, the most significant increase is that associated with the support of research activities.

It is of interest to note that 16 medical schools anticipate grants-in-aid for research and teaching from outside sources in excess of $1,000,000 and that 7 of these present estimates in excess of $2,000,000. Further analysis of data available reveals that 15 of the four year medical schools anticipate income from such grants for research and teaching from outside sources in excess of their basic total operating medical school budgets. Table 7 is a recapitulation of estimated funds available to medical schools in the United States for 1955-1956 for basic operating budgets and from grants from outside sources for research and teaching. In comparing this total of $159,519,515 with that of $148,645,201 for the 1954-1955 period, it should again be emphasized that the new total includes an additional four year school and two schools of basic medical sciences in transition to four year programs.

Costs in connection with the activities of basic medical education, like costs in other fields, have continued to increase. While some institutions have enjoyed modest augmentation of funds for basic operational costs, this has not been true of others which continue to encounter very difficult financing. Institutions where 50% or more of the basic operational budget is dependent upon tuition and fees face particularly difficult financial problems. Average tuition rates would seem to be at an almost maximum level consistent with the ability of medical students and their families to meet them and the other costs involved, such as board and room, laundry, transportation, and miscellaneous expenses.

The financing of research in association with medical school activities presents an interesting picture today. Medical schools furnish physical facilities and some equipment, as well as the time and effort of costly faculty personnel for research. However, data obtained from the annual questionnaire indicate that in budgeting, 23 of the medical schools have allocated a total of $1,563,184 to the direct support of research activities from the basic operating budget. This implies that well over 95% of the expenditures for the important research activities that are now being conducted in medical schools are met by the $54,470,989 obtained from grants for research from outside agencies. It should be reemphasized that medical schools basically support research to a larger degree than is represented by the direct allocation of $1,563,184, through the facilities and equipment they furnish, as well as the faculty personnel, time, and effort allocated to such activities. However, the available data clearly highlight the fact that the current research activity is almost totally dependent on outside sources for financial support, and that these sources have become an increasingly essential factor in the development and maintenance of medical research.

Because of its steadily increasing role and significance in the support of medical research and special teaching projects over the past decade, the United States Public Health Service was requested to prepare a summary of the educational values of its grant and award programs during this period. The tabulation and informative summary on the next page which was prepared by officials of the National Institutes of Health, will be of interest to all individuals and organizations concerned with medical education and research. It clearly illustrates that the partnership role of the Public Health Service in the promotion of medical education and medical research has been increasingly substantial in nature and is essential to the maintenance of the current high level of investigative activity as well as certain teaching activities of the medical schools.

TABLE 7.—*Estimated Funds Available to Medical Schools, 1955-1956*

(This does not include funds for construction, which are summarized in table 5, nor does it include operational costs of major clinical facilities.)

Category	Amount
Basic budgeted funds and appropriations (table 6)..	$ 98,012,621
Research grants from outside sources..................	54,470,989
Teaching grants from outside sources.................	7,035,905
Total	$159,519,515

EDUCATIONAL VALUES OF THE GRANT AND AWARD PROGRAMS OF THE UNITED STATES PUBLIC HEALTH SERVICE

Unprecedented scientific achievement during World War II led to general appreciation of the benefits to be derived from intensive programs of medical research and education. Such programs to be of maximum value must seek new basic knowledge and apply it to the understanding of major health problems, notably those arising as infectious diseases decline and the life span lengthens. To help meet this need, Congress has increased its appropriation to the Public Health Service's research bureau, the National Institutes of Health, from $2,835,000 for 1945 to $97,573,000 for 1956. Approximately two-thirds of each year's appropriation is awarded to nonfederal institutions, agencies, and individuals, largely for the support of research projects and the development of scientific manpower.

The National Institutes of Health, located at Bethesda, Md., comprises seven institutes organized to support and conduct research on the major chronic and infectious diseases. The program areas include heart disease, cancer, mental disorders, neurological diseases and blindness, arthritis and metabolic diseases, dental diseases, and microbiological problems. Serving the various institutes is the Division of Research Grants and the Clinical Center, a 500-bed facility for clinical-laboratory research. Over the past decade, the National Institutes of Health has assumed an important place in the nation's medical science structure. The scope of its support is indicated by the tabulation below:

TABLE 7A.—*National Institutes of Health History of Appropriations for Grants and Awards Combined Programs, Fiscal Years 1945-1956*

Yr.	Training Awards	Research Fellowships	Research Grants
1945	$ 29,000	$ 28,000	$ 85,030
1946	25,000	44,600	780,158
1947	250,000	178,000	3,576,198
1948	2,809,700	520,000	9,145,000
1949	3,930,000	1,115,000	10,671,492
1950	6,415,060	1,448,057	13,065,514
1951	6,928,200	1,565,000	16,713,000
1952	7,392,000	1,755,000	18,173,000
1953	8,194,000	2,024,000	20,374,000
1954	10,813,000	2,133,000	28,866,000
1955	11,051,000	2,562,000	33,918,000
1956	14,502,000	2,800,000	38,038,000

Training Grants.—Research manpower bears a crucial relation to the nation's health, for the quality and volume of medical research is directly proportional to the caliber and number of workers devoted to the medical and biological sciences. Closely related to the growing problem of manpower shortage in these fields is the need for physicians with special competence in the treatment of major chronic diseases. National Institutes of Health grants for training and teaching provide direct aid to educational institutions. They help schools equip medical students and professionals in certain related areas with the latest medical knowledge. Although awarded for a one year period, the grants have been uniformly renewed upon request. They are available from the National Cancer Institute, National Heart Institute, National Institute of Mental Health, National Institute of Arthritis and Metabolic Diseases, and National Institute of Neurological Diseases and Blindness.

The first three of these institutes award grants for the support of training at undergraduate levels. The specific purpose is to establish, expand, improve, or continue instruction related to health problems within the institute's program. Applicants that have received grants to date include schools of medicine, dentistry, and public health. The present maximums for grants in this category range from $5,000 for teaching of cancer in dental schools to $25,000 for cancer or heart grants to four year medical colleges.

Graduate training grants are awarded through the National Heart Institute and the national institutes of arthritis and metabolic diseases, neurological diseases and blindness, and mental health. These awards have a two-fold purpose, to help the schools improve their instructional programs and to make funds available for trainees' stipends. In the case of the National Institute of Menta Health, grants are made to training institutions for: (1 instructional and other expenses of training, (2) aid t trainees in the payment of expenses, and (3) researc with a view to evaluating and developing instruction methods. The subjects covered are psychiatry, clinic psychology, psychiatric social work, psychiatric nursin and public health. Support may be requested for a ma imum of five years.

In the cancer field, where National Institutes of Heal training grants were first employed, some typical resul have been the acquisition and retention of superior i structors, improved teaching practices including wid use of visual aids, establishment of cytology and isoto laboratories, increased awareness of cancer on the p of both faculty and students, and more thorough utiliz tion of available knowledge. Every medical school in t country is participating. Cancer coordinators, designat by the schools, have been an important factor in ganizing and rounding out the teaching programs.

Traineeships.—In addition to the trainee stipen awarded locally out of training grants, the Public Hea Service offers direct traineeships through the Natio Cancer Institute, National Heart Institute, National stitute of Arthritis and Metabolic Diseases, and Natio Institute of Neurological Diseases and Blindness. Th awards are intended to increase the number of physici and allied workers engaged in specialized clinical tivities. They are of two types: regular traineeships qualified citizens with an appropriate doctoral deg ($3,400 the first year and $3,700 the second year, p $350 per dependent child and spouse), and spec traineeships (in varying amounts) to citizens with u usual competence or in need of specialized training fo specific problem. They are generally made for one ye but may be renewed and permit the trainee to study the institution of his choice.

Research Fellowships.—The research fellowships p gram of the National Institutes of Health provides fina cial assistance to promising American scientists duri their training period, so that they can pursue careers medical research and allied fields. These fellowships a awarded on a competitive basis upon the recommend tion of scientific committees. A research fellow may co duct his work at any institution where interest, guidanc and facilities are suitable. Nine out of 10 fellowship cipients remain in medical research after their training

Four classes of research fellowship are available: (1 predoctoral, (2) postdoctoral, (3) special, and (4) th medical and dental student part-time research fellowsh grant. Predoctoral research fellowships are awarded qualified persons with a bachelor's degree intending prepare for graduate training in a health science. Annu stipends range from $1,400 to $1,800, plus $350 per de pendent child and spouse. Postdoctoral research fellow ships require an M.D., Ph.D., D.D.S., or equivale degree. The stipend is $3,400 the first year and $3,70 the second, plus $350 per dependent. Special researc fellowships require unusual competence for research o specialized training, as well as a doctor's degree in medicine, dentistry, or related fields, and the stipend is determined at the time of award. Fellowships of the fourth-listed class are awarded to acceptable medical or dental schools in units of $400 each. Medical schools may request up to four units and dental schools up to two, plus an additional 8% allowance for indirect costs. The award may cover part-time activities of a selected student during the school year or full-time activities during the summer vacation. (Other fellowship allowances include the $500 supply grant to an institution sponsoring postdoctoral or special fellows, tuition provided as part of a fellowship award, and expenses for certain travel.)

Research Grants.—The most extensive National Institutes of Health program in terms of expenditure, the research grants program, has been not only a forceful stimulus and aid to medical research, but has also contributed significantly to the education of junior participants in the grant projects. Tremendous expansion of the program has been accompanied by increased research support from various sources and by dispersion of research throughout the country's medical schools, universities, and hospitals. This year, support is being given to 372 research institutions in 47 states, the District of Columbia, 2 territories, and 9 foreign countries.

All seven institutes award grants to support research projects within their particular fields, and the Division of Research Grants is responsible for grants not encompassed by any institute's program. During the fiscal year 1955, 3,261 research grants were awarded. (These support 731 projects in heart research, 720 in cancer, 432 in arthritis and metabolic diseases, 400 in neurology, 236 in microbiology, 223 in mental health, 49 in dental, and 470 in subjects outside these areas.) In addition, cancer field investigation grants totaled 86. Because of the acute shortage of research personnel in psychiatry, career investigator grants were recently established by the National Institute of Mental Health. These are special research grants to assist in opening research careers to qualified young psychiatrists and scientists in related disciplines by providing three to five year support for full-time research at the recipient institution.

Primarily, the purpose of the research grants program is to expand research in medical schools, hospitals, and other nonprofit institutions, and to stimulate new investigation in neglected fields. Research grant applications are reviewed by panels composed largely of nonfederal scientific specialists, and the awards are made only upon the recommendation of appropriate national advisory councils. The several councils are composed of nonfederal leaders in science, education, and public affairs. (Further information and application forms may be obtained from the national institute concerned. For research fellowship applications, write to the Division of Research Grants, National Institutes of Health, Bethesda 14, Md.

Visiting Scientist Program.—The purpose and spirit of the visiting scientist program is to increase the utility of the National Institutes of Health as a national research resource and to strengthen interrelations with the broader scientific community. Two levels of appointment have been established: (1) visiting scientist and (2) research associate in the visiting scientist program. Both awards require a doctoral degree or equivalent training and experience. In addition, the visiting scientist must have outstanding ability and at least six years' postgraduate experience in research. The caliber of both recipients must be such that their work at the National Institutes of Health would be mutually beneficial to themselves and the staff.

Conferences and Symposiums.—In addition to the obvious educational components of the grants and training awards, these programs afford educational opportunities through the full or partial support of congresses, seminars, and symposiums related to the field under scrutiny. For example, the Heart Institute aided in the Second World Congress of Cardiology, which assembled the current cardiovascular knowledge of 50 nations. The Institute of Neurological Diseases and Blindness participated in a special conference of the American League Against Epilepsy, which recommended changes in state laws affecting 1,500,000 epileptics. Among the conferences sponsored or cosponsored by the National Cancer Institute have been the National Cancer Conference, the Sixth National Gastrointestinal Cancer Conference, and the Annual Cancer Coordinator's Conference. The National Institute of Mental Health supports meetings to exchange information on particular mental health subjects, to provide orientation and training in specific services, and to review and develop curriculums, functions, and standards for various professions. As part of its continuing educational program, the National Institutes of Health provides personnel and exhibits for medical and scientific meetings of state, regional, and national scope.

Increasingly, National Institutes of Health clinical conferences, lectures, and seminars are attracting the active participation of physicians from private practice, faculty members of universities and medical schools, and staffs of other service hospitals and research centers. As a net result, the National Institutes of Health participates in the educational contribution of institutions of higher learning in the biomedical sciences.

MEDICAL SCHOOL FACULTIES

For the past several years the Council has presented a résumé of data in regard to currently unfilled teaching positions in medical schools in the United States. Table 8 summarizes the information submitted by schools as projected for 1955-1956. In the basic medical sciences fields the medical schools report 32 new and 76 old, or a total of 108, authorized and budgeted positions currently unfilled in their faculties. Clinical departments report 82 new and 61 old, a total of 143 unfilled positions. Distribution according to rank reveals that 53 of the vacancies are professorships, 52 associate professorships, 79 assistant professorships, 60 instructorships and 7 assistants or associate positions. The total number of vacancies reported is seven less than the number recorded for 1954-1955. In view of the newly developing programs and new faculty appointments that have been made during the past year, this slight improvement in unfilled posts is perhaps more significant than it appears on the surface. However, as the new school programs undergo further development, the need for faculty personnel will continue to increase. Recruitment of highly qualified medical faculty full-time personnel promises to continue as a challenge to medical education.

Because of increasing interest in the problems associated with the financing of clinical faculty personnel, last year's annual report included for the first time an analysis of the status of faculty personnel in clinical departments. In recent years there has been considerable misunderstanding on the part of many individuals as to the implication of the term "geographical full-time" in connection with clinical faculty appointments. As ordinarily utilized it implies that the individual faculty member conducts all of his activities in the "geographical" environment of the medical school. The institution usually pays a basic salary to the faculty member in this category, and he is permitted to have additional income from consultations or from private practice conducted in addition to his teaching, administrative, and research responsibilities. Because of the costliness of financing absolute full-time clinical personnel receiving salaries with no other income from professional activities and the accompanying limitations, relatively few institutions have found it possible to maintain adequate clinical faculty personnel without the utilization of some form of "geographical" arrangements.

On the basis of information currently available, it would appear that the manner in which clinical faculty personnel are employed must depend upon the peculiar needs of each individual school. Problems of medical school financing reveal that there is no single answer suitable or applicable to all institutions and that arrangements must be made at the local level that serve the best interests of the school and maintain its relations with the local medical profession, from which the average institution must derive much of its clinical instruction. Conscientious study, thorough understanding, and satisfactory communication between medical schools and medical professional organizations in any given locale should make it possible to develop plans for the employment of clinical faculty personnel as nearly mutually satisfactory to all concerned as possible.

It is important, however, to note in passing that problems centered around this area of medical school functions have in some instances led to serious misunderstanding and difficulties between professional and school groups. It has resulted in the introduction of a resolution to the House of Delegates of the American Medical Association in 1954 on the part of one state medical association directed against "the practice of medicine" by personnel of tax-supported medical schools and requesting the establishment of a definite over-all policy covering employment of medical faculty members in such institutions.

Subsequently the Council on Medical Service of the American Medical Association was asked to conduct an inquiry into the practices of medical schools in the employment of clinical faculty personnel. In conference with representatives of the Council on Medical Education and Hospitals, the Association of American Medical Colleges, and the American Hospital Association, a questionnaire was designed to obtain comprehensive information from the medical schools. The Council on Medical Service has also designed a questionnaire for the medical societies in locations where medical schools exist. The results of these questionnaires are being analyzed, and a report of the findings will be made in the near future. It is to be hoped that this information will be of great value in clarifying some of the areas of misunderstanding and allaying some of the misapprehensions that have appeared with increasing frequency in recent years.

It is not easy to develop and retain high caliber medical faculty personnel in either basic medical science or clinical areas. It is important that members of the medical profession in the locale of a medical school fully understand and appreciate the problems of the school and that the school in turn have full knowledge and appreciation of the problems of the profession. Only through mutual confidence in the integrity of each, through established and satisfactory mechanisms for review of misunderstandings and difficulties, and through concerted effort to adjust them satisfactorily can these problems be minimized or eliminated.

CURRICULUM STUDIES

Legal Medicine, Medical Ethics, Economic Aspects of Medicine, Medical Public Relations, and Medical History.—In each annual report on medical education in the United States and Canada, it is planned to present information on certain facets of the medical school curriculum content. The questionnaire this year included an inquiry on the number of hours specifically allocated to, and departments responsible for, instruction in legal medicine, medical ethics, economic aspects of medicine, medical public relations, and medical history. If no specific allocations of time for instruction in any of these areas were included in the curriculum, a request was made as to what method was utilized to develop background knowledge of their importance in medicine today.

Information from the medical schools indicates that 70 of the 81 institutions in the United States allocate definite time to the teaching of legal medicine. This varies from a minimum of one hour to a maximum of 42 hours. Forty-five of the schools allocate over 10 hours and six of this group assign over 20 hours in this field. The average allocation is 12.5 hours for the 70 schools offering specifically assigned teaching time. With the exception of 3 two year schools of basic medical science and 1 four year institution, the remaining group of 11 medical schools indicate that instruction in this field is incorporated in one way or another with other phases of medical education. There is no uniform pattern of handling instruction in legal medicine. Institutions report that this subject matter is taught by departments of legal and/or forensic medicine, preventive medicine, public health, medicine, pathology, pharmacology, neurology, the medical school administration, school of law, a university institute of government, and by special lecturers.

All but six of the four year schools and three of the schools of basic medical science indicate that instruction is given in some form in the field of medical ethics. Only 40 of the 81 schools, however, indicate specific allocations of time, which vary in amount from 2 to 64 hours. Where it is allocated specific time in the curriculum, it is given as medical ethics, cultural medicine, medical law and ethics, public relations, philosophy of medicine, or social and environmental medicine. It is presented by the dean or other administrative officers, by departments of medicine, public health, preventive medicine, cooperatively by several departments, or by medical societies. Those institutions where specific time is not allocated but where some attention is given to student indoctrination indicate that a number of different methods are used. For instance, the faculty of one institution believes medical ethics and medical public relations are aspects of medical knowledge best gained through observation and discussions with small groups of students in class, on the wards, and in clinics. Another indicates that medical ethics, economics, and public relations are integrated with clinical teaching and are conveyed principally by precept. A third accomplishes its purpose through specifically assigned correlation conferences and through creating awareness of the need by day to day teaching within other established courses. In some schools awareness of the importance of the field of ethics is introduced early in the first year through orientation lectures and conferences. In at least three medical schools the local or state medical societies are cooperating in the conduct of lectures and discussions in the fields of medical ethics and medical public relations.

There are nine four-year schools and four schools of basic medical science which report no time allocation for, or specific instruction in, the economic aspects of medicine. All the other institutions indicate that this field receives coverage in connection with such courses as public health, preventive medicine, medical ethics, social and environmental medicine, and legal and economic medicine, through lectures, conferences, and discussions by the dean, or by cooperation with local or state medical societies. Specific allocation of time in 33 schools indicates that consideration of the economic aspects of medicine is assigned from a minimum of one to a maximum of 24 hours.

Twenty-one of the 81 approved medical schools in the United States specifically allocate from one to 11 hours to consideration of medical public relations. Twenty-three of the schools allocate no specific time, nor do they indicate the incorporation of instruction in this field in connection with other courses. All the remaining institutions indicate that some emphasis is given to medical public relations in connection with instruction in one or more departments.

Most reports emphasize the importance of constant presentation of ethics, economics, and public relations as an integral part of all phases of undergraduate medical education in the precept and example of teachers and members of the profession with whom students have contact.

Seventy-one of the medical schools offer either required or elective work in the field of medical history. Time allocations vary from 2 to 50 hours. These courses are conducted by departments of medical history, cultural medicine, medicine, surgery, anatomy, public health, pathology, physiology, preventive medicine, and social and environmental medicine and in orientation courses. In a number of institutions, medical history is an interdepartmental offering, and in two schools the course is conducted by the American College of Physicians. In a few schools efforts are made to highlight important historical events in connection with individual departmental teaching. Ten of the schools report no time allocation for either required or elective work in medical history or any indication of its conscious integration into other courses.

NATIONAL FUND FOR MEDICAL EDUCATION AND AMERICAN MEDICAL EDUCATION FOUNDATION

The 1954 annual report of the National Fund for Medical Education indicates that business, industry, and other segments of society, together with physicians who gave funds through the American Medical Education Foundation, contributed a total of $2,693,170. Grants totaling $2,176,905 were made in July, 1954, to the 80 medical schools approved at the time, which brought the total distribution to approximately $7,000,000 since the initial grants were made in 1951.

During 1954, Public Law 685 granting a federal charter to the National Fund for Medical Education was enacted by Congress. This was recognition by Congress that medical education is of vital national concern and that the fund's role in mobilizing voluntary support for the strengthening of our medical schools is deserving of broad national backing.

The 1954 Annual Report of the American Medical Education Foundation indicates that $3,563,881 of the total funds disbursed to medical schools from 1951 to 1954 were obtained from this source. During the period

1951-1954, the American Medical Association contributed $500,000 annually for a total of $2,000,000. Physicians voluntarily contributed an additional $1,357,638, medical societies and associations $553,662, and others $7,682. At the time the American Medical Education Foundation was instituted, it was understood that, as individual physician contributions increased in number, the American Medical Association would reduce its annual direct contribution. The Board of Trustees of the American Medical Association has reduced its direct contribution to $100,000 this year, while continuing to underwrite the costs of the American Medical Education Foundation program. It is to be hoped that both the American Medical Education Foundation and the National Fund for Medical Education will rapidly gain both in number of contributors and in total contributions.

PRECEPTORSHIPS

Data about preceptorships were supplied for 1954-1955 by the schools as to: (1) whether or not they were included in the curriculum, (2) year established, (3) whether or not preceptors were general practitioners, specialists, or both, (4) whether they were required or elective, (5) their duration, and (6) the number of students participating. In addition, institutions indicated the preceptorship's objectives and means utilized to determine whether the stated objectives were being fulfilled.

TABLE 9.—*Preceptorship Programs, 1954-1955*

Institutions	Yr. Established
University of Arkansas	1952
College of Medical Evangelists	1952
University of California	1952
Stritch School of Medicine	1951
Indiana University	1953
State University of Iowa	1953
University of Kansas	1950
University of Louisville	1952
Boston University	1948
University of Nebraska	1951
Albany Medical College	1952
University of Buffalo	1950
Duke University	1938
Western Reserve University	1952
University of Oklahoma	1949
University of Oregon	1952
Hahnemann Medical College	1953
Temple University	1954
University of Pennsylvania	1950
University of South Dakota	1947
University of Texas	1952
University of Vermont	1929
University of Washington	1949
University of Wisconsin	1926

In 1954-1955, a total of 24 schools offered preceptorships, compared to 22 in 1953-1954. Emory University discontinued its program, Stritch reinstated its preceptorship, Temple established its program, and Western Reserve continued a program established in 1952 that had not been previously reported. Table 9 lists the institutions offering preceptorships in 1954-1955 and the years in which the programs were established. In 15 of the programs, preceptors are general practitioners, and in 6 they are reported to be specialists, while both participate in the remainder of the programs. Preceptorships are offered in the fourth year in 18 schools, in the third year in 3, in the third or fourth year in 1, in the second year in 1, and in all four years in 1 institution. They are required in 10 and elective in 14 schools. Length of preceptorships varies from two weeks to four and one-half months. In 1954-1955, 1,433 students participated in preceptorship programs.

The statements submitted in regard to the objectives sought in the preceptorship program, although varied in their mode of presentation, indicated, in general, a desire *to offer students an opportunity* to observe closely medical practice as *it* is actually carried out. The program *is believed to afford the students* an opportunity to investigate certain types of practice in which they ma desire a career, as well as to provide an opportunit to appreciate the scientific, social, economic, and environmental factors in the practice of medicine. On institution expressed its desire to teach the student "medical way of life," and another tersely indicated i objectives to be identical with those of its over-a undergraduate programs of offering the best possib basic educational experience for its students.

The various methods utilized to evaluate precepto ships include reports from preceptors and precepte and routine evaluations by deans or committees. Oth institutions have utilized polls of students, precepto *and former students who have taken preceptorships.* O *institution utilizes questionnaires and conferences* wi students, an annual conference with preceptors, a adequate liaison between the school administration a preceptors through visits to the preceptors.

The impression is received that preceptorships ha been considered as valuable experiences when the pr grams were well planned and preceptors were carefu selected and thoroughly cognizant of the objectives the program, as well as interested in it. One instituti indicated that students did not seem to be interested or satisfied with the program and that doctors did n understand the functions of a preceptorship. As was i *dicated in connection with the editorial discussions* *family care programs last year,* preceptorship opportu ities can be only as good as the planning, personnel, a supervision, and such programs deserve the over- study and implementation which will make it possib to realize their maximum potentialities as part of undergraduate medical educational experience.

TEACHING RESPONSIBILITIES FOR OTHER THAN UNDERGRADUATE MEDICAL STUDENTS

1954-1955

In addition to their responsibilities in undergradua medical education, all the medical schools in the Unit States and all but one in Canada instruct students other classifications. The number of individuals oth than undergraduate medical students *who receive* all part of their instruction from medical *faculties* continu *in 1954-1955 to be twice as great as the total* number undergraduate medical students. For 1954-1955 t medical schools in the United States reported 57,27 students other than undergraduate medical students, an Canadian schools reported 6,211 such students. Th represented a decline of 2,107 in the United State schools and an increase of 930 in the Canadian school Table 10 analyzes the number and *distribution* of stu dents other than undergraduate medical registrants fo whom *medical schools have teaching* responsibilities.

* Some of these may also be candidates for Ph.D. degrees.

The greatest increases in 1954-1955 in the United States schools were in connection with continuation courses for physicians in which 3,504 more were enrolled than in the previous year and an increase of 575 dental students over those registered 1953-1954. There were decreases in arts and science students (2,580), nursing students (465) and student technicians (231). Graduate students working towards advanced degrees in basic medical sciences and clinical areas constitute an important and challenging aspect of medical school responsibility. This phase of medical school activity is discussed more fully in the section of this report dealing with graduate medical education.

As was suggested in the last Education Number of The Journal, the teaching responsibilities of medical schools for other than undergraduate medical students carry significant budget and personnel implications that necessitate full interpretation by responsible administrators. Interpretation of the true cost of medical education necessitates the evaluation of these other teaching activities and their deduction from over-all budgets where they are included in medical school accounting. The assumption of any teaching responsibility implies the need for adequate personnel, so that the teaching and research activities of a department are not diluted to the point where undergraduate medical students, other students, or both may have less effective opportunities than might otherwise be the case.

Table 11.—*Schools, Students, and Graduates in the Medical and Basic Sciences Schools in the United States, 1931-1955*

Too frequently when a medical school renders service functions to large numbers of students in other areas, either no adjustment or a nominal financial adjustment is made, ostensibly to pay for such services. Frequently such reimbursements fall far short of the actual cost of the services rendered and leave the medical school underwriting the difference, with this additional load interpreted by the uninformed as part of the cost of medical education. This problem appears to fall in the area of budget and accounting practices of medical schools and universities. The true cost of educating undergraduate medical students in a complex university setting or wherever others are also taught by the school can be determined only by utilizing effective budget and accounting methods.

The question as to whether teaching responsibilities for other than undergraduate medical students may unduly dilute either teaching or research, or both, is a matter of local institutional policy. If a medical school administration is fully aware of the implication of additional teaching services from the standpoint of budget, personnel, and facilities and such needs are satisfied, there is no logical reason why either teaching or research in medicine should be diluted in any sense. In fact, with adequate budgets, personnel, and facilities, departments of basic medical sciences carrying such responsibilities may possess even greater potential in both teaching and research than would be the case if their activities were restricted solely to undergraduate medical students and to graduate students in their specific fields.

Medical Students

ENROLLMENTS

For the sixth consecutive year, the number of students enrolled in approved medical schools in the United States has established a new record. Complete enrollment data for the individual schools are shown in table 1 and comparative data for this and preceding years are given in table 11.

It should be noted that the figure in table 1 depicting total enrollment for this past year includes 142 special or part-time students, whereas in previous years only full-time students were shown. However, even when this type of student is deleted from the current data, there remains an increase of slightly less than 1%. Approximately two-thirds of the increase is accounted for by the addition of information on the University of California School of Medicine at Los Angeles, which this year had all four classes in attendance and gained approval by the Council on Medical Education and Hospitals.

The entering class was the largest ever enrolled in our schools, and only half the increase over last year is accounted for by the addition of the class at the University of California School of Medicine at Los Angeles. The most significant changes in size of the entering class occurred at the Medical College of Georgia with an increase from 79 to 101 and the University of Maryland with a decrease from 104 to 88 first year students.

The University of Miami School of Medicine in 1954-1955 had the first three classes in attendance, and it is anticipated that this school will be eligible for approval during the 1955-1956 academic year, thus promising new enrollment records again for next year.

Five schools had a total enrollment greater than 600 students. The University of Tennessee College of Medicine led in this respect with a total enrollment of 804. The University of Tennessee and the University of Michigan admitted more than 200 students to their entering classes (221 and 205 respectively). There were six additional schools with first year enrollments of 150 or more students.

The median first year class for the four year schools was composed of 87 students, and the average had 98 students. The median total enrollment was 338 and the average 375 students. The schools of basic medical sciences had an average entering class of 39.

Enrollment data for approved Canadian medical schools are given in table 2. Comparison of this with similar data for last year reveals a very small increase in both total enrollment and numbers of first year medical students. Those students enrolled in the premedical year and required intern year are not included in the total enrollment in table 2.

It is pertinent to note that 82 United States citizens were enrolled in the first medical year in Canadian schools as compared to 4 Canadian citizens enrolled in the first year class of United States medical schools (table 12). More detailed information in regard to this can be found in the next section of this report.

GEOGRAPHICAL SOURCE OF ENTERING STUDENTS

Information as to the state of permanent residence for entering students was derived from the enrollment data submitted by the medical schools. Table 12 presents the residence of students at the time of their enrollment in the approved medical schools in the United States and Canada.

This table indicates that 41% of all first years students in the United States came from six states (New York, Pennsylvania, California, Ohio, Illinois, and Texas). It is interesting to note that the first year enrollment of all of the medical schools in these states represented 42% of the total enrollment, and that 38% of all medical schools are located in the same states.

There were less than 20 first year students in the medical schools in the United States from each of six states (Nevada, Delaware, Wyoming, New Hampshire, New Mexico, and Montana). The 76 students from these states represented only 1% of the total first year class. There are no medical schools in the six states concerned.

In table 13 are listed the states in ascending order according to the number of enrolled first year medical students per 100,000 population. The six states with the largest number of first year students are well scattered through this list, with half having less than the median number of students per 100,000 population (4.4) and half having more. The six states with the smallest number of first year students enrolled in medical schools, on the other hand, in all instances have fewer students than the median, and five of them are included in the eight states with the lowest freshman medical student representation.

Since last year's report, four states (Vermont, Rhode Island, South Dakota, and Utah) have all gained one or more first year students per 100,000 population. This is balanced by four other states (Nevada, Montana, Florida, and Arkansas) whose student per population ratio decreased by a similar amount.

There were 12 state and one city-owned school that limited enrollment to students who were residents of that state in which the schools were located. It is perhaps pertinent that other residents of these same states, equal in number to 34% of the first year enrollment of these 13 schools, were accepted in medical schools outside their own states. Legislative bodies perhaps should consider the effect that adoption by all medical schools of similarly complete restrictive admission policies would have on the numbers of their own residents who would be able to acquire a medical education. Attention is directed to the section on attrition, where the possible relationships between geographical restrictive admission policies, applications to medical schools, and attrition due to poor scholarship are discussed.

The section of table 12 that depicts the state of residence of students in Canadian medical schools is worthy of notice, for it brings out a fact that has been given little attention. There are 80 United States students enrolled in the first medical year of the Canadian schools. Since there are only four Canadian students in the first year class of our own schools, we are the recipient of a favorable balance that represents an educational opportunity equivalent to another medical school.

United States first year medical students in Canada come from 22 different states with New York (21), Massachusetts (11), and California (11) accounting for more than half of such students. All but two of the Canadian schools are involved, and McGill has 58 United States students in the first medical year. This is more than the first year enrollment in seven of our own approved four year schools and is larger than the entering class in any of our schools of basic medical sciences.

ENROLLMENT OF WOMEN STUDENTS

Information by school on the number of men and women students enrolled and graduated can be found in table 14. Jefferson and Dartmouth continued to limit enrollment to men, and Woman's Medical College enrolled only women students.

The number of women students attending medical school was slightly greater than the previous year, but the number of women graduates in the year covered by this report was the smallest since 1947.

Excluding Woman's Medical College, medical schools of three universities (Columbia; State University of New York, New York City; and University of Tennessee) enrolled 40 or more women, and in four schools (Howard, Columbia, University of Wisconsin, and University of Puerto Rico), women accounted for 10% or more of the total enrollment. Women represented 10% or more of the graduating class in six schools (University of Colorado, Howard, Louisiana State University, Southwestern, University of Wisconsin, and University of Puerto Rico).

Table 15 indicates the number and percentage of women enrolled and graduated by year since 1905. Although there is little evidence of significant change in recent years, the increased enrollment for the past two years may suggest that the absolute and relative decrease in women graduates will be of short duration.

MILITARY LIABILITY OF MALE MEDICAL STUDENTS

In the questionnaire sent to all approved medical schools, each school was asked to classify male students according to whether or not they had any military liability under the Universal Military Service and Training Act, as amended. Male students who had no basic liability for military service were defined as those person

who had: (1) between Dec. 7, 1941, and Sept. 7, 1945, served on active military duty in excess of 90 days; or (2) between Sept. 16, 1940, and June 24, 1948, served on active military duty in the armed forces for more than one year; or (3) after June 24, 1948, served on active military duty in the armed forces for two years or more and ended service with an honorable discharge.

Table 16 presents data showing by class the number of male students with and without military liability based on the definitions given above. It is not possible to compare the data with veteran and nonveteran enrollment published in preceding years since different definitions were used.

Male students liable for military service comprised 82% of the first year class, 83% of the second year, 80% of the third year, and 73% of the fourth year.

† State with no approved medical school.

It is to be noted that the number cited as liable for service makes no allowance for physical disabilities and other factors that would render an unknown percentage ineligible for service.

PREPROFESSIONAL REQUIREMENTS AND ATTAINMENTS OF THE ENTERING CLASS

Since January, 1953, the minimum requirement for admission to an approved medical school has been three years of college preparatory study. The Council on Medical Education and Hospitals in accepting this minimum recommends for most students a full four year college course in order that a broader background education may be obtained. In its "Essentials of an Acceptable Medical School" the Council also makes provision for the unusually intelligent and mature student, stating that "rarely a school will be justified in admitting a superior student under exceptional conditions after two years of college work."

For purposes of this report, medical schools were asked to stipulate the minimum number of years of col-

TABLE 16.—*Military Liability of Male Medical Students, 1954-1955*

	First Yr.	Second Yr.	Third Yr.	Fourth Yr.	Totals
Men with no military liability	1,282	1,130	1,336	1,795	5,543
Men with military liability	5,857	5,589	5,251	4,806	21,503
Total enrollment	7,139	6,719	6,587	6,601	27,046

Study of these tables reveals that what several schools reported as minimal requirements might be better termed usual requirements, since of the eight schools that specified four years of college as a prerequisite to admission, six admitted students with three years of college work. Conversely, of the five schools that admitted only students who had four years of college, three stipulated three years as the minimal requirement. Thus, one might presume that in these instances the usual requirement is four years. This is in keeping with the general practice of medical schools as a group, since 75% of all students in the entering class had had four years of college. Twenty-five per cent had had three years of college study, and no one was admitted with only two years.

Totals	7,576	1,880	5,696	5,403	71.1

Only a relatively few schools mention the baccalaureate degree as a condition of admission. Of those that do, some specify that the degree must be obtained before matriculating in medical school, and others make it permissive to obtain the degree any time up to the beginning of the second medical school year. Four schools admitted only students holding degrees at the time of matriculation; and only two of these schools specify this as a requirement. Since 75% of the entering students had had four college years, it is not surprising that 70% held a baccalaureate degree at the time of matriculation. Previous experience indicates that another 15-20% will later acquire the degree, earned on work done in part in the medical school.

COLLEGE RECORD

Table 18 compares the college scholastic record of the entering class of 1954-1955 with that of 1953-1954. It is evident that there has been a small decrease in the number of admitted students with a 3.6-4.0 (A) record with an equivalent increase in the number of students with a 1.0-2.5 (C) record. The college record of this year's class is very similar to that of 1952-1953.

Inquiries addressed to this Council illustrate the need for emphasizing that college academic achievement as measured by scholastic records is only one factor used in the selection of medical students. Over a period of years, most if not all medical schools admit students with an over-all college average of "C" when other factors appear to justify such action.

TABLE 18.—*Comparison of College Record, Freshman Class, 1953-1954 and 1954-1955*

College Grade Average	Percentage of 1953-1954 Freshman Class	Percentage of 1954-1955 Freshman Class
3.6-4.0 (A)	21.1	16.8
2.6-3.5 (B)	68.9	69.0
1.0-2.5 (C)	10.0	14.2

TRANSFER OF STUDENTS FROM SCHOOLS OF BASIC MEDICAL SCIENCES TO FOUR YEAR MEDICAL SCHOOLS

In last year's report data was given showing the medical schools which accepted graduates of the basic medical sciences schools as transfer students with advanced standing. This data covered a five year period (1949-1953) and revealed that all such students during this period were successfully transferred. It is planned to collect similar data every five years, and in the interim students and their faculty advisors in the schools of basic medical sciences are advised to consult the 54th Annual Report on Medical Education.

ATTRITION OF MEDICAL STUDENTS

In the last annual report, a section was devoted to student losses for the academic year 1952-1953. This year it was possible to obtain from the medical schools data on student attrition for the academic year 1954-1955 covered by this report, and it is planned to publish similar current information in succeeding reports so that losses in any given class can be shown throughout the four years that class is in medical school.

Table 19 depicts by class and cause students lost to medicine during 1954-1955. Comparison of these figures with those for 1952-1953 reveals remarkable constancy in the percentage of total losses in each class and the total losses in relationship to the total enrollment for the years concerned.

Two-thirds of all losses were in the first year class and 62% of those losses were due to failure or withdrawal in poor academic standing. In the second year class, losses due to poor academic standing or failure represented 66% of all losses, but, in both the third and fourth year classes, more than two-thirds of the losses were students who withdrew in good academic standing. This discrepancy as to cause of attrition between the first two and last two classes was evident in the previous study, and it again seems valid to point out that withdrawals in good academic standing during the last years of medical school study represent a challenge to improve counseling and perhaps to a need for better sources of financial assistance. Students who are unable to maintain acceptable academic records represent a necessary loss, but those whose academic achievement is satisfactory and who withdraw for other causes in many instances must represent a loss that could and probably should be avoided.

TABLE 19.—*Attrition in the Approved Medical Schools in the United States, 1954-1955*

	Enrollment	Failed	Withdrew, Poor Standing	Withdrew, Good Standing	Totals	Percentage of Enrollment Lost
First year	7,576	200	58	161	419	5.5
Second year	7,104	79	7	45	131	1.8
Third year	6,957	18	1	42	61	0.8
Fourth year	6,946	4	3	17	24	0.3
Totals	28,583	301	69	265	635	

In last year's report a possible relationship between losses due to unsatisfactory scholastic achievement and admission policies imposing geographical restrictions was brought out. Data for 1954-1955 appear to offer further evidence in support of this observation.

Table 20 shows, by type of school ownership, data referable to enrollments, applications, and attrition due to unsatisfactory scholarship for the first year class.

TABLE 20.—*First Year Enrollments, Applications, and Attrition with Poor Scholarship by Type of School Ownership, 1954-1955*

	State or Municipally Owned	Privately Owned
No. of schools *	39	41
Percentage of enrollment	50	50
Percentage of enrollment from out of state	9	53
Percentage of applications	26	74
Percentage of failures and withdrawals in poor academic standing	70	30

* Puerto Rico figures not available.

It can be seen that the total first year enrollment was shared equally by public and private schools. The entering students in public schools were largely residents of the states in which the schools are located; whereas, more than half the students entering private schools were out-of-state residents.

It is also evident that public schools had a much smaller percentage of the total applications to consider in selecting their first year class. Although this appears to be a valid observation, the discrepancy is modified to some degree by fact that applicants to private schools tend to file more applications than do those to public schools (table 21). Figures in table 20 refer to applications not applicants.

Lastly, it is to be noted that a large percentage of all student failures and withdrawals in poor academic standing occur in the public schools. Certainly there is no proof available that this is directly related to the other data presented. With no evidence to the contrary, however, it does seem reasonable to consider that there is a suggestive relationship between admission policies restrictive on a geographical basis with a smaller population from which to draw first year medical students and a higher incidence of student losses with poor academic records.

THE NEXT ENTERING CLASS

Information currently available suggests that in 1955-1956 there will be little if any significant change in the number of openings available in the first year classes of existing approved medical schools. The Medical School at Miami University is expected to be eligible for approval during the coming year, and figures for its first year as well as all other classes will be included in the next report. The Albert Einstein College of Medicine at Yeshiva University will enroll its first class for the academic year 1955-1956, and subsequently its students will enlarge the number for next year's first year classes.

The number of applicants for the study of medicine has decreased annually for the past five years.[11] It is encouraging to note that the increment of loss this year was considerably less than in the previous four years, so that it may be hoped that a plateau has been reached. If there should be a continuing decrease in the number of applicants for medical schools, it is possible the schools will not be able to fill all available openings with qualified candidates.

GRADUATES

There was again a record number of graduates of approved medical schools in the United States. The 6,977 graduates of this year represent an increase of 1.7% over last year. Almost half of the increase was due to the discontinuation of the required internship at Stanford so that there were two graduating classes at that institution. Approximately one-quarter of the increase was the result of the addition of the class at the newly approved School of Medicine of the University of California at Los Angeles, and the remaining quarter was due to an increase in the size of graduating classes at other schools.

Four medical schools (Tennessee, Michigan, Illinois, and Jefferson) each graduated more than 150 students, and five schools (University of California, Los Angeles; Woman's Medical; Puerto Rico; Vermont; and Vanderbilt) had fewer than 50 students in their graduating classes.

Information in regard to the number of graduates each year since 1930 can be found in table 11. With

TABLE 21.—*Number of Completed Applications Acted upon by Each Medical School and the Total Number of Applications Filed by These Applicants, 1954-1955* *

	Size of Freshman Class	Applicants to Each Medical School			Total Applications Filed by Applicants to Each School	Average Number of Applications per Applicant

---

[11] Stalnaker, J. M., and Dykman, R. A.: The Study of Applicants, Association of American Medical Colleges, to be published.

some yearly variation, there has been a gradual increase so that the current graduating class is almost 50% larger than that of 25 years ago.

The third year class of 1954-1955 was slightly smaller than that of the preceding year, now the current graduating class. It is anticipated that the School of Medicine of Miami will be eligible for approval during the academic year 1955-1956 and its students and graduates incorporated in next year's report. Since the graduating class at Miami will not entirely compensate for the difference in size of these two classes, it can be predicted that next year's graduating class will probably be slightly smaller than the one for this year. However, because classes scheduled for graduation in subsequent years are somewhat larger and because of new schools in development, any decrease that does occur will be only an incident in a continuing expanding number of graduates in the years ahead.

Of this year's graduates, 88.6% held baccalaureate degrees at the time of graduation. As first year students, only 70% of the same class had this degree, so that approximately one-sixth of the class earned their college degrees partly on the basis of work completed in medical school.

TABLE 22.—*Students in the Required Intern Year in the United States, 1931-1955*

Yr.	No.	Yr.	No.
1930-1931	1,025	1943-1944	451
1931-1932	1,067	1944 (2nd session)	447
1932-1933	1,106	1944-1945	452
1933-1934	1,183	1945-1946	488

1942-1943	639	1954-1955	50

* Includes additional classes.

REQUIRED INTERN YEAR

The trend toward abandoning the internship as a requirement for graduation was brought out in last year's report and is illustrated in table 22. In 1954-1955 only Stanford continued to require an internship for graduation, and it has made the decision to eliminate this requirement and award the medical degree at the successful completion of four years of medical school study. Thus, after this year, there will be no students serving internships as a prerequisite to graduation.

Almost all new graduates continue to serve internships, and there is no indication that the elimination of this as a requirement of the medical schools for graduation has produced any trend away from the internship as a step in the medical education process.

STUDENT FEES

Fees for resident and nonresident students charged by each medical school are listed in table 1. During the year covered by this report, the average tuition fee for resident students was $646 and for nonresident students was $807. Comparable figures for last year were $633 and $722.

SCHOLARSHIP AND LOAN FUNDS IN UNITED STATES MEDICAL SCHOOLS

Seventy-one of the 81 medical schools in the United States have either student scholarship or loan funds, or both, available. Since the report of last year covering the 1953-1954 academic session, 10 schools have increased their total available scholarship funds by $108,200. Eleven schools have augmented loan funds by $202,330. Thus, for 1954-1955, 71 schools had a total of $1,151,760 available for student scholarships and $2,332,170 for loans.

Three of the schools received additional scholarship funds in excess of $20,000 for the year. One of the state university medical schools received additional loan funds of $100,000 for the year.

The Council on Rural Health of the American Medical Association has prepared a brochure on the medical scholarship and loan fund programs available only to the residents of the 17 sponsoring states including Alabama, Connecticut, Georgia, Idaho, Illinois, Iowa, Kansas, Kentucky, Michigan, Minnesota, Mississippi, Missouri, Nebraska, Ohio, Pennsylvania, South Dakota, and Wisconsin. This brochure itemizes the scholarship and loan funds sponsored or administered by state and county medical societies, women's auxiliaries, joint medical society and state boards, and special organizations. It does not include medical school grants, state scholarships and loans not connected with medical societies, and private endowments.

What Happens to Medical School Graduates?

NEW STUDY BY BUREAU OF MEDICAL ECONOMIC RESEARCH

In connection with the tabulation of statistical data, the Bureau of Medical Economic Research of the American Medical Association has accumulated vast quantities of information of interest and value in the field of medical education. It maintains a continuous census of physicians on punch cards coextensive with the files of the Directory Department. That Department has great difficulty in keeping abreast of the changes in addresses and type of practice of American physicians. Some interns, for example, are not reclassified until many months after completing their internships because of their delay in notifying the Directory Department.

Last year the Bureau of Medical Economic Research published Bulletin 94, Distribution of Physicians by Medical Service Areas, as a result of its six year cooperative study with the state medical societies. It was necessary to relate all data to April, 1950, the effective date of the 1950 United States Census of Population, in computing population-physician ratios. Since the code numbers for the medical school and the year of graduation were punched into each of the 205,000 cards for the physicians living in the 48 states and the District of Columbia, the Bureau decided to sort the cards by school and prepare approximately 500 tables. In 7 of the 11 groups of tables there are 72 separate tables, one for each of the 72 schools approved at that time. This statistical study of the medical school alumni will be published in Bureau of Medical Economic Research

Publication M-94 in the fall of 1955. It will present for the first time a comprehensive picture of the distribution of the alumni of each of the 72 United States approved (as of April, 1950) four year medical schools and of the 72 schools as a group, by type of practice, by state, by size of city, and by year of graduation and some similar data for three groups of schools—other United States schools (184), the Canadian schools (13) and foreign schools (226). A follow-up study for 1956 is being planned, which will probably include additional data on specialization and data on the alumni of approved United States medical schools residing in Canada and the United States possessions, in addition to those residing in the states.

Table 23 is the first or basic table of this forthcoming study and is presented in this issue of THE JOURNAL to acquaint medical educators with the potentialities inherent in the report. The type-of-practice distributions by four groups of schools are shown in three parts. (Limitations on these type-of-practice data cannot be set forth herein, they will be described fully in the forthcoming Bureau publication.) Part A deals with numbers; part B with percentage distribution by school grouping; and part C with percentage distribution by type of practice. Of the 205,000 physicians, 164,409, or 80.2%, were graduates of the 72 United States approved four year schools, 13.2% were graduates of other United States schools, 2.0% of Canadian schools, and 4.6% of foreign schools. These four over-all percentages are the basic frame of reference for comparisons. (The 214 early graduates of some of the seven approved two year schools were included among the 27,066 total for other United States schools.) It is anticipated that the percentage for foreign schools will be higher in the 1956 survey.

Of the 76,158 general practitioners in April 1950, only 56,000, or 73.5%, were graduates of the 72 approved United States four year schools; of all physicians, less than 80.2% were graduates of the approved schools. On the other hand, the graduates of the other United States schools accounted for 18.8% of the general practitioners, but only 13.2% of the total physicians. (Some of the tables in the forthcoming Bureau of Medical Economic Research Publication M-94 will show that these graduates were older and less concentrated in the large cities.)

Similar comparisons can be made from the percentages in part B for the other types of practice. For example, the graduates of the 72 approved four year schools accounted for 84.2% of the full-time specialists, relatively more than the 80.2% of all physicians. The graduates of the Canadian schools accounted for a relatively larger proportion of full-time specialists, 2.4% versus 2.0% of all physicians, and a relatively small proportion of the general practitioners, 1.8% versus 2.0%. The pattern for the foreign school graduates in this regard follows somewhat the pattern of the graduates of other United States schools, namely, a relatively larger proportion of general practitioners, 5.9% versus 4.6%. Considerably above the over-all percentage of 80.2%, 88.1% of the full-time medical school staff members were graduates of the 72 approved United States four year schools. As might be expected, an inordinately high percentage, 34.6%, of the retired and not in practice group were graduates of other United States schools, a fact which indicates, of course, that many of them were in the higher age brackets.

TABLE 23.—*Type-of-Practice Distribution by School Groupings*

Type of Practice * (1)	Approved U.S. 4 Yr. Medical Schools (2)	Other U.S. Medical Schools (3)	Canadian Medical Schools (4)	Foreign Medical Schools (5)	Total (6)
A. Number					
1. General practitioners	56,000	14,278	1,381	4,499	76,158
2. Part-time specialists	18,341	3,261	451	1,207	23,260
3. Full-time specialists	48,022	5,057	1,398	2,557	57,034
1-2-3. Active private practice	(122,363)	(22,596)	(3,230)	(8,263)	(156,452)
4. Administration, research, industry, local government	813	108	41	52	1,014
5. Full-time medical school staff	1,558	84	51	76	1,769
6. Federal government	9,156	542	130	415	10,243
7. Retired and not in practice	6,366	3,604	215	237	10,422
8. Interns	8,612	12	117	42	8,783
9. Residents	15,541	120	336	310	16,307
Total physicians	164,409	27,066	4,120	9,395	205,000
B. Percentage Distribution by School Groupings					
1. General practitioners	73.5%	18.8%	1.8%	5.9%	100.0%
2. Part-time specialists	78.9	14.0	1.9	5.2	100.0
3. Full-time specialists	84.2	8.9	2.4	4.5	100.0
1-2-3. Active private practice	(78.2)	(14.4)	(2.1)	(5.3)	(100.0)
4. Administration, research, industry, local government	80.2	10.7	4.0	5.1	100.0
5. Full-time medical school staff	88.1	4.7	2.9	4.3	100.0
6. Federal government	89.4	5.3	1.3	4.0	100.0
7. Retired and not in practice	61.1	34.6	2.0	2.3	100.0
8. Interns	98.1	0.1	1.3	0.5	100.0
9. Residents	95.3	0.7	2.1	1.9	100.0
Total physicians	80.2	13.2	2.0	4.6	100.0
C. Percentage Distribution by Type of Practice					
1. General practitioners	34.1%	52.8%	33.5%	47.9%	37.2%
2. Part-time specialists	11.1	12.0	11.0	12.9	11.3
3. Full-time specialists	29.2	18.7	33.9	27.2	27.8
1-2-3. Active private practice	(74.4)	(83.5)	(78.4)	(88.0)	(76.3)
4. *Administration, research,* industry, local government	0.5	0.4	1.0	0.6	0.5
5. Full-time medical school staff	0.9	0.3	1.2	0.8	0.9
6. Federal government	5.6	2.0	3.2	4.4	5.0
7. Retired and not in practice	3.9	13 3	5.2	2.5	5.1
8. Interns	5.2	0.1	2.8	0.4	4.3
9. Residents	9.5	0.4	8.2	3.3	7.9
Total physicians	100.0	100.0	100.0	100.0	100.0

---

* Definitions used in these nine classifications and limitations on the source data, particularly on interns and residents, are found in Bureau of Medical Economic Research Publication M-94.

In part C, 100.0% represents the total for the graduates of each of the four groups of schools with the percentage distribution of the four groups combined in the right-hand column. Of the total physicians, 37.2% were general practitioners, while of the alumni of the 72 United States approved four year schools 34.1% were general practitioners, as were 52.8% of the alumni of the other United States schools, 33.5% of the alumni of the Canadian schools, and 47.9% of the alumni of the foreign schools. An atypically low percentage (18.7% versus 27.8%) and an atypically high percentage (33.9% versus 27.8%) of the alumni of the other United States schools and Canadian schools respectively were full-time specialists.

The Bureau of Medical Economic Research indicated that further observation based on this single table would raise more questions than they could or would be able to answer. The forthcoming study Bureau of Medical Economic Research Publication M-94 will contain much information of interest to medical educators. The comparative data that is being prepared for each of the approved medical schools (as of April, 1950) will be of particular value. Only one copy will be available to each medical school, as only 100 copies will be planographed.

Medical Education and National Defense

CURRENT STATUS

The Joint Committee on Medical Education in Time of National Emergency, representing the Council on Medical Education and Hospitals of the American Medical Association and the Association of American Medical Colleges, has continued to collaborate as closely as possible with the Department of Defense, the armed forces, the Selective Service System, the Public Health Service, the Civil Administration, and other governmental agencies in considering problems created for medical education by the continuing defense needs of the nation.

The Council on Medical Education and Hospitals and the American Medical Association as well as the Association of American Medical Colleges supported the legislative proposals in regard to the development of medical military scholarships. The concept of medical military scholarships, however, has not received congressional support. Some members of Congress apparently favor the establishment of a military medical academy or school rather than the support of medical military scholarships, unless the latter involves a definite commitment for increased undergraduate student enrollment.

The program for medical education and national defense (MEND) has been given additional support and will be extended. A full-time national coordinator for the program has been appointed with offices maintained in the Bureau of Medicine and Surgery, Department of the Navy, Potomac Annex, Washington, D. C.

Following the two year pilot study program at the colleges of medicine of Cornell, Buffalo, Vanderbilt, Illinois, and the University of California at San Francisco, the MEND program has been extended to ten additional schools. This additional list includes Baylor, Colorado, Emory, Georgetown, Medical College of Virginia, Ohio State, Pennsylvania, Tufts, Washington at Seattle, and Wisconsin. Ten more schools are to be added in January, 1956.

MEND is a function of the Joint Committee on Medical Education in Time of National Emergency, representing the Council on *Medical Education and Hospitals* of the American Medical Association and the Association of American Medical Colleges. Its program has been endorsed by both parent organizations, as well as by the medical officials of the Department of Defense, Public Health Service, and Federal Civil Defense Administration.

The purpose of the program is to encourage the teaching of principles of military and disaster medicine by regular faculty members of the medical colleges. Nothing is mandatory, each faculty is free to accept or reject any part of the program not consistent with the local philosophy of medical education. All emphasis is on medical rather than military topics.

Features of the program include symposiums for the faculties of participating institutions sponsored by the MEND committee. During 1955-1956, a three day session on aviation physiology and medicine will be conducted by the Air Force at Randolph Field, Texas, in October. Later symposiums will include infectious diseases, chemical, biological, and radiological warfare defense, and surgery of trauma. Faculty members are offered opportunities to visit research installations of the federal services to learn of recent developments in military areas of activity.

SELECTIVE SERVICE SYSTEM AND DEFERMENT ELIGIBILITY

The responsibility for primary classification of registrants rests with selective service local boards. If a person or his employer (college, medical school, or hospital) has requested his deferment and he has been classified as available for military service, the person or his employer may, within ten days of the mailing of the notice of classification, file an appeal. If the State Appeal Board should sustain the classification, the registrant or his employer may, if there is a dissenting vote in the appeal board, file a written request with the local board to have the decision appealed to the National Selective Service Appeal Board. If there is no dissenting vote, the state or national director of selective service may appeal the case to the President.

The "college student certificate," SSS Form 109, continues to be prescribed for the use of institutions of higher learning, including those of medicine, in furnishing the local boards information regarding registrants who are enrolled as students in those institutions. These forms should be submitted to the local boards by the educational institution on request of the registrant. However, the mere filing of such a form does not constitute a request for occupational deferment, since, in order to establish the right of appeal as an interested party, a written request from the college or employer for occupational deferment must accompany the form. The registrant has the right of appeal if exercised in the prescribed ten days. He may make his appeal informally in writing.

ELIGIBILITY FOR CONSIDERATION FOR DEFERMENT

The law empowers the President to provide for the deferment of any person whose deferment is equitable and in the national interest. Furthermore, it is the sense of Congress that provision should be made for the annual deferment from training and service of premedical, pre-dental, and allied preprofessional students in numbers equal to those at present in attendance at colleges and universities as outlined in the general student deferment program. The President is also directed to establish a national advisory committee to advise the Selective Service System and assist state and local advisory boards in selecting the needed medical, dental, and allied personnel.

Sections 1622:15 and 1622:25 of the Selective Service Regulations specify the conditions under which students pursuing programs of higher education may be considered for deferment. Within these specified requirements, students of the healing arts are considered for deferment in the same manner as students pursuing other undergraduate or graduate courses at colleges, universities, and similar schools.

Any student not previously deferred who is pursuing a full-time course of study is entitled to a single period of statutory deferment, Class 1-S, until the end of the academic year. Such deferment does not preclude the possibility of later deferment in Class 2-S. Students whose activity in study, research, medical, or other endeavors is found necessary to maintenance of the national health, safety, or interest may be deferred in Class 2-S until completion of their training, provided they maintain satisfactory scholastic records. A student who is deferred for study extends his liability for military training and service up to his 35th birthday instead of his 26th as prescribed for registrants who have never enjoyed a deferment.

In selecting a student for deferment in Class 2-S, the Selective Service local boards may, at their discretion, be guided either by the score made by the student on the Selective Service College Qualification Test or by his record of academic performance.

The College Qualification Test is given for the Selective Service System by the Science Research Associates, Inc., of Chicago. At present, in order to be eligible for deferment on the basis of this test, an undergraduate student must make a score of 70 or more. SSS Form 108 has been prescribed for furnishing to the local board the score made on this test. This score is confidential and may be divulged by the local board only to the registrant or one holding his written consent.

To qualify for deferment on the basis of academic performance, the nonprofessional student must have maintained the following standing among the male members of his class; freshman year, upper one-half; sophomore year, upper two-thirds; junior year, upper three-fourths.

A student accepted for admission to medical school after July 1, 1951, for the class next commencing may be deferred provided that, during his last full-time year at a college or university, he was ranked among the upper one-half of the male members of his class or had a score of 70 or more on the Selective Service College Qualification Test.

A student accepted for admission by a graduate school after July 1, 1951, as a full-time student for the class next commencing may be deferred provided in his last full-time academic year in a college or university he achieved a scholarship standing among the upper one-half of the male members of his class or scored 75 or more on the qualification test and provided the graduate school certifies that he is meeting the degree requirements.

Decisions concerning deferment of American students enrolled in foreign universities, including medical students, are the responsibility of the local boards. The local board may accept or reject any claims or evidence presented for deferment.

STATUS OF INTERNS AND RESIDENTS

The Selective Service System has always recommended the deferment of graduates of medicine to complete one year of internship training. Recently, and in order to prevent calling up men of priority 3 who are in the higher age brackets, Selective Service has stated that men to be given favorable consideration for deferment to complete a residency or more than one year of internship, should be absolutely essential to the operation or maintenance of the hospitals where they are employed. Selective Service is of the opinion that there is a sufficient number of priority 4 young men to fill the needs of hospitals for residents.

For the fiscal year 1956 (July 1, 1955-June 30, 1956), the National Advisory Committee to the Selective Service System has agreed to request that local boards defer 300 men who finish their internships on or about June 30, 1955, for the purpose of residency training in some specialty. These 300 men are all to be commissioned in the reserve component of one of the armed forces, and they are to be selected by the Assistant Secretary of Defense (Health and Medical) for such training. The request for deferment is to pass from the individual to the Assistant Secretary of Defense (Health and Medical) and then, if recommended, will be forwarded through national headquarters of the Selective Service System to the respective local boards of that system. This program may be continued in subsequent years. The number of such requested deferments is to be determined year by year.

The National Advisory Committee to the Selective Service System has indicated that all physicians in priority 1 and priority 2 and those in priority 3 born after August 30, 1922, will be needed by the armed forces and has advised that they apply for commissions about the time of completion of their internships. A few persons in these categories may be recommended for deferment by the Selective Service local boards for teaching, research, or public health or because they are rendering essential service in isolated communities and cannot be replaced.

In addition, the only persons in this group who can justifiably be recommended for deferment are those who are accepted for training in the scarcity specialties and whose services are required to meet the essential needs of medical and dental schools or hospital services. The specialties in which critical shortages exist are anesthesiology, physical medicine and rehabilitation, psychiatry, radiology, neurology, pathology, public health, orthopedic surgery, oral surgery, and the basic medical sciences. Those few persons in these groups for whom deferment is necessary may be deferred in Class 2-A by the Selective Service local boards. The recommendation of the advisory groups in all such cases is desirable.

STATUS OF FACULTY MEMBERS

Since the majority of the faculty members of medical schools are under 50 years of age, they are required to register with the Selective Service System as indicated under Public Law 779. No policy has been announced by the Selective Service System on the granting of deferment to faculty members, except that recently teachers of medicine have been mentioned in a Selective Service operations bulletin as being in a critical occupation to which local boards should give special consideration. The National Advisory Committee has recommended that, as a general policy, essential members of medical, dental, and veterinary faculties be held in their teaching positions until such time as replacements are found. This recommendation applies especially to persons in the basic sciences departments and includes persons in priorities 1 and 2. This policy is not a blanket recommendation for deferment from military service for all teachers. Part-time teachers, who devote only a small portion of their time to teaching, and certain of the younger full-time teachers in priorities 1 and 2 will be expected to enter the military services.

CURRENT STATUS OF THE "DOCTOR-DRAFT" LAW

The "Doctor-Draft" law was first approved Sept. 9, 1950, as Public Law 779, 81st Congress, an amendment to the Universal Military Training and Service Act. It has subsequently been amended by Public Law 84, 83rd Congress, approved June 19, 1953; Public Law 403, 83rd Congress, approved June 18, 1954; and Public Law 118, 84th Congress, approved June 30, 1955. These amendments, which have been included as Section 4(i) of the Universal Military Training and Service Act, are known as the "Doctor-Draft" law.

The effective date of the Universal Military Training and Service Act, as now amended, is extended to July 1, 1959, while that part pertaining to the registration and induction of physicians, dentists, and allied specialists ("Doctor-Draft" law) is extended to July 1, 1957. No change was made in the age limit prescribed in the previous amendments which required that all physicians, dentists, and allied specialists under the age of 50 must register with the Selective Service System local boards when required to do so by the proclamation of the President. Therefore, all new medical graduates under the age of 50 must register with their Selective Service local boards as physicians, regardless of any previous registration, within five days of the receipt of the Degree of Doctor of Medicine, provided they do not hold a commission in an armed forces reserve component. However, Public Law 118, of the 84th Congress, did relieve any physician who had attained the 46th anniversary of his birth from liability of induction. When the degree is not granted by the school until completion of an internship, this special registration is accordingly deferred.

As under previous provisions of the act, registrants will be arranged in four priorities signifying the order of induction. However, the criteria for such an arrangement under these priorities have been modified. The major changes enacted by the new amendments are those which provide for greater recognition of prior military service. A registrant will now receive credit for all service performed as either an officer or enlisted man since Sept. 16, 1940, regardless of whether it was before or after participation in an AST or V-12 program, or deferment by the Selective Service System for professional education prior to March 31, 1947. Also, recognition is given for military service performed in the armed services of a country allied with the United States prior to Sept. 2, 1945, while so allied.

Whereas, formerly physicians who were educated in part or in whole at government expense or were deferred by the Selective Service System while completing their professional education needed 21 months of service to qualify for assignment in priority 4, they now need only 17 months. As a result of this change, a number of physicians formerly in priorities 1 and 2 have been reassigned in priority 4. The periods of service for men called to active duty or inducted under the new law were also revised. Those with 9 months or less of service must serve 24 months. Those with 9 to 12 months will serve 21 months. Those with 12 to 15 months' service will serve 18 months, and those with 15 to 21 months will serve 15 months. Those physicians in priority 4 who have had 21 months or more of service since Sept. 16, 1940, are not liable to induction or recall, except in time of war or national emergency declared by Congress.

"Active service" and "active duty" are defined as full-time duty since Sept. 16, 1940, in the service of the United States Army, Navy, Air Force, Marine Corps, Coast Guard, or Public Health Service, including reserve components; time spent during World War II by conscientious objectors in work of national importance; service performed before Sept. 2, 1945, in the armed forces of countries that were allies of the United States during World War II; and service performed as a physician or dentist for the Panama Canal Health Department between Sept. 16, 1940, and Sept. 2, 1945.

Specifically excluded from consideration as "active service" is time spent in V-12 or AST programs in military internships, residencies, or senior student programs, time spent in military service for the sole purpose of undergoing physical examination, and training entered into after June 29, 1953. The law continues to permit deferment of those persons whose activities are essential to the national health, safety, or interest.

It is the duty of the National Advisory Committee and the voluntary state and local committees of the Selective Service System to make recommendations to the Selective Service System concerning the essentiality or availability of special registrants who are being classified by their local boards. This duty includes recommendations concerning residents, faculty members, and those engaged in essential laboratory and clinical research.

Public Law 403, approved June 18, 1954, amended the so-called "Doctor-Draft" law and makes it possible for the armed forces to return to duty, but in enlisted status, persons serving under the "Doctor-Draft" law whose loyalty is questioned or for security reasons. This amendment, therefore, removed the mandatory requirement of Public Law 84 that physicians and dentists be given commissions.

The latest amendment, Public Law 118, 84th Congress, provides that if any physician special registrant, after attaining the 35th anniversary of the date of his birth, applies or has applied for a commission in one of the armed forces as such and is or has been rejected for commission on the sole grounds of physical disqualification, he is not liable for induction.

Role of Medical Schools in Graduate and Continuation Education

As knowledge in the field of science applicable to teaching, research, and the practice of medicine continues to increase with accelerating rapidity the potential role of medical schools in the field of continuation education becomes more apparent and more important. Many years ago John Chalmers De Costa wrote to the effect that: "Each one of us, however old, is still an undergraduate in the school of experience. When a man thinks he has graduated he becomes a public menace." In the dynamic field of medicine no individual who teaches or practices can ever cease seeking further knowledge, learning new techniques, and developing the wisdom to utilize them effectively.

Over the past several years the Council on Medical Education and Hospitals has endeavored to assist physicians in their search for opportunities in continuation education through the semiannual listing of courses, clinics, and other activities planned and scheduled by medical schools, hospitals, medical societies, specialty organizations, and clinics. Beginning this year the list will be an annual presentation covering the period from Sept. 1 to Aug. 31 of the succeeding year. The first annual listing appeared in the July 23, 1955, issue of THE JOURNAL. Supplementary listings will appear from time to time, the first one represented by table 24 in this publication.

All medical schools conducting programs of undergraduate medical education are also naturally involved in graduate medical education through either direct administrative responsibility or through activities of their faculty personnel in the planning and supervision of graduate students, interns, and residents. This area of medical school responsibility has steadily increased over the years. In many institutions undergraduate and graduate medical education are intimately interwoven. Faculty, interns, and residents participate in the supervision of student clinical clerks, and in some institutions the latter are considered to be junior components of the medical team as they conduct their clinical assignments.

INTERNSHIPS AND RESIDENCIES

In the current list of approved internships and residencies in THE JOURNAL (Sept. 24, 1955) an analysis was made of internships based on the participation of the hospital in undergraduate medical education. This is summarized in table 25. It was indicated that 213 hospitals approved for internships (25% of the 850 so approved) were designated as either major (140) or minor (73) teaching hospitals in their medical school relationship. The 140 major teaching hospitals offered 4,017 (36%) of the total approved internships (11,048) and the 73 minor teaching affiliations accounted for 849 (7.7%). Thus 43.7% of all of the approved internships were in institutions affiliated with medical schools where faculty personnel were directly involved in the supervision and conduct of training programs. Eighty-five per cent of the internships in major teaching hospitals, 81% of those in minor teaching hospitals, and 80% of approved internships in nonaffiliated hospitals were filled last year.

The current list of approved internships and residencies indicates that in 1954-1955 there were 25,486 residencies available at all levels, of which 20,494 (80%) were filled. An exact analysis of the number of residents in medical school affiliated hospitals as compared to those in nonaffiliated institutions is not available. However, it is fair to assume that medical school faculty personnel carry a heavy load of responsibility for planning and supervising graduate medical education at the residency level.

INCREASING INTEREST IN THE INTERNSHIP

During recent years increasing attention has been centered on the internship by members of the medical profession and hospital administrators as well as by medical educators. On several occasions the House of Delegates of the American Medical Association has appointed special committees to study the internship. The most recent of these committees was the Ad Hoc Committee, which after thorough study reported its findings and recommendations to the House of Delegates during the past year (December, 1954, and June, 1955). This committee clearly upheld the primary educational function of the internship in its final recommendations. At the June, 1955, meeting of the House of Delegates of the American Medical Association, two resolutions were approved which publicly recorded professional support of the educational objective of the internship. One of these resolutions is of such general importance as an expression of professional opinion as to the nature of the internship that it is recorded, herewith:

> WHEREAS, Different ideas concerning the purpose of the internship have led to confusion as to what should be its proper content of experience and its proper place in the field of hospital organization and in the general scheme of medical education; and
>
> WHEREAS, It seems desirable that the medical profession through action of the House of Delegates, should take clarifying action to establish publicly its attitude toward these matters;
>
> THEREFORE BE IT
>
> *Resolved*, It is the sense of the House of Delegates that the following principles be given general recognition:
>
> First, that the internship in fact combines two functions, (1) as an educational period in the training of young physicians and (2) as a position rendering medical care and service to patients in hospitals and assistance to the staffs of the hospitals.

TABLE 24.—*Postgraduate Courses for Physicians*

Postgraduate Instruction for Physicians—Sept. 1, 1955, to Aug. 31, 1956

Course Code No.	Title of Course	Location of Course	Type	Designed for	Total Hours	Methods of Instruction	Starting Date	Time Arrangements	Fee in Dollars
ANESTHESIOLOGY									
P 04114	Short Course in Anaesthesia,[1, 2, 3]	Victoria General Hospital Tower Road Halifax, Nova Scotia	R	G	26	Clinical case work Lecture or panel	2/27/56	C; 4 days	20
CARDIOVASCULAR DISEASE									
P 04546	Electrocardiography [3]	University of California School of Medicine Los Angeles	R	G	15	Lecture or panel	3/29/56	C; 15 hr.	50
DERMATOLOGY									
P 02939	Dermatology in General Practice [3, 16]	University of California School of Medicine Los Angeles	R	G	12	Clinical case work Lecture or panel	11/ 9/55	I; 2 hr. weekly for 6 wk. Wednesdays	30
P 02940	Dermatology in General Practice [3, 20]	University of California School of Medicine Los Angeles	R	G	12	Clinical case work Lecture or panel	2/15/56	I; 2 hr. weekly for 6 wk. Wednesdays	30
P 04417	Symposium in Dermatology [1, 2, 3]	Victoria General Hospital Tower Road Halifax, Nova Scotia	R	G	13	Lecture or panel	4/9/56	C; 2 days	10
GENERAL MEDICINE									
P 02933	Aviation Medicine	University of California School of Medicine Los Angeles	S	G	21	Lecture or panel	10/25/55	C; 3 days	50
P 02122	Medicine for Today [3, 27, 28]	St. James Hospital Chicago Heights, Ill.	R	G	24	Lecture or panel	10/ 4/55	I; 2 hr. weekly for 12 wk. Tuesdays	40
P 02123	Medicine for Today [3, 27, 28]	Wabash General Hospital Mt. Carmel, Ill.	R	G	24	Lecture or panel	10/ 6/55	I; 2 hr. weekly for 12 wk. Thursdays	40
P 03722	Recent Advances in General Medicine [3, 21, 22]	University of Cincinnati College of Medicine Eden and Bethesda Aves. Cincinnati 19	R	G	12	Lecture or panel	10/ 6/55	I; 3 hr. weekly for 4 wk. Thursdays	10
P 03723	Rehabilitation in Chronic Diseases [3, 21, 22]	Sheltering Oaks 408 Union St. Cincinnati	R	G	5	Lecture or panel	11/27/55	C; 5 hr.	10
P 05022	Bridgewater Regional Course [1, 3, 7]	Selected center in Bridgewater, Nova Scotia	R	G	15	Lecture or panel Demonstration	11/55	I; 3 hr. weekly for 5 wk. Fridays	10
P 04024	Kentville Regional Course [1, 3, 7]	Selected center in Kentville, Nova Scotia	R	G	18	Lecture or panel Demonstration	3/56	I; 3 hr. weekly for 6 wk. Wednesdays	10
P 05025	New Glasgow Regional Course [1, 3, 7]	Selected center in New Glasgow, Nova Scotia	R	G	15	Lecture or panel Demonstration	4/56	I; 3 hr. weekly for 5 wk. Fridays	10
GYNECOLOGY									
P 04413	Week in Obstetrics, Gynecology and Pediatrics [1, 3, 5, 6]	Victoria General Hospital Halifax, Nova Scotia Grace Maternity Hospital Halifax, Nova Scotia Children's Hospital Halifax, Nova Scotia	R	G	31	Clinical case work Operative surgery	11/21/55	C; 5 days	25
P 05027	Short Course in Obstetrics and Gynecology [1]	Selected center in Nova Scotia	R	G	Unknown	Unknown	5/17/56	C; 2 days	Unknown
INDUSTRIAL MEDICINE									
P 02773	Application of Principles of Industrial Medicine to Private	University of California School of	S	G	18	Lecture or panel	10/19/55	I; 2 hr. weekly for wk. Wednesdays	60

			INTERNAL MEDICINE						
P 03828	Physiological Basis of Internal Medicine [3,11,12,13]	Duke University School of Medicine Durham, N. C.	S	S	10	Lecture or panel	10/10/55	C; 5 days	30 to members
P 01110	Week in Medicine [1,2,3,4]	Victoria General Hospital Tower Road Halifax, Nova Scotia	R	G	31	Clinical case work Lecture or panel	3/26/56	C; 5 days	25
			MALIGNANT DISEASE						
P 02488	Midwest Cancer Conference [8,9,10]	Hotel Broadview Wichita, Kan.	R	B	15	Lecture or panel Demonstration	3/22/56	Specially arranged	Nil
			NEUROLOGY						
P 03724	Neuro-Psychiatry [3,21,22]	Hotel Gibson Cincinnati	R	G	4	Lecture or panel	1/22/56	C; 4 hr.	10
			OBSTETRICS						
P 01966	Obstetrics [3,17]	University of California Riverside Campus Riverside, Calif.	R	G	6	Lecture or panel	10/ 5/55	C; 1 day	17.50
P 04413	Week in Obstetrics, Gynecology and Pediatrics [1,3,5,6]	Victoria General Hospital Halifax, Nova Scotia Grace Maternity Hospital Halifax, Nova Scotia Children's Hospital Halifax, Nova Scotia	R	G	31	Clinical case work Operative Surgery	11/21/55	C; 5 days	25
P 05027	Short Course in Obstetrics and Gynecology [1]	Selected center in Nova Scotia	R	G	Unknown	Unknown	5/17/56	C; 2 days	Unknown
			OPHTHALMOLOGY						
P 01305	Postgraduate Series in Ophthalmology	Yale University School of Medicine 333 Cedar St. New Haven, Conn.	R	S	10	Lecture or panel	11/18/55	I; 1 hr. every 2 wk. for 5 mo. Fridays	15
P 03799	Postgraduate Convention of the Oregon Academy of Ophthalmology and Otolaryngology	University of Oregon Medical School 3181 S.W. Sam Jackson Park Rd. Portland 1, Ore.	R	B	15	Lecture or panel Demonstration	3/19/56	C; 2½ days	85
P 03800	Postgraduate Convention of the Oregon Academy of Ophthalmology and Otolaryngology	University of Oregon Medical School 3181 S.W. Sam Jackson Park Rd. Portland 1, Ore.	R	B	15	Lecture or panel Demonstration	3/23/56	C; 2½ days	85
P 04283	Virginia Society of Ophthalmology and Otolaryngology—Clinical Session [3,24,25,26]	Medical College of Virginia Box 25, 1200 E. Broad St. Richmond 19, Va.	R	B	32	Lecture or panel	11/29/55	C; 4 days	35
			OTOLARYNGOLOGY						
P 03729	Twentieth Annual Graduate Convention in Otology, Rhinology, and Laryngology [23]	University of Cincinnati College of Medicine Eden and Bethesda Aves. Cincinnati 19	S	S	45	Laboratory work Operative surgery	4/16/56	C; 5½ days	150
P 03799	Postgraduate Convention of the Oregon Academy of Ophthalmology and Otolaryngology	University of Oregon Medical School 3181 S.W. Sam Jackson Park Rd. Portland 1, Ore.	R	B	15	Lecture or panel	3/19/56	C; 2½ days	85
P 04283	Virginia Society of Ophthalmology and Otolaryngology—Clinical Session [3,24,25,26]	Medical College of Virginia Box 25, 1200 E. Broad St. Richmond 19, Va.	R	B	32	Lecture or panel	11/29/55	C; 4 days	35
			PATHOLOGY						
P 04545	General Surgical Pathology [3]	University of California School of Medicine Los Angeles	R	G	36	Laboratory work Lecture or panel	11/12/55	I; 4 hr. weekly for 9 wk. Saturdays	80
			PEDIATRICS						
P 02935	Pediatrics [3]	University of California School of Medicine Los Angeles	R	G	15	Lecture or panel	10/27/55	C; 3 days	50

Miscellaneous

3. Certificate given.

4. Neurology, Rheumatology, and Physical Medicine and Rehabilitation featured.

5. Of the 31 hours, 11½ are Pediatrics.

13. Fee for members $30; nonmembers $60.

18. Combined session—P-01378 (Plastic Repair of Superficial Wounds) held in afternoon; P-02368 (Burns) held in morning. Fee for entire day $17.50.

22. $10 for one seminar; $25 for four seminars (members).

20. Four day course, two days Ophthalmology and two days Otolaryngology; fee $20 for half, $35 for all.

Second, that its educational function is of primary and paramount importance and that its service function is secondary and incidental.

Third, that its educational function should be recognized as possessing a character of its own and should not be regarded as an additional year of medical school nor as the first year of a narrowly specialized professional career.

Fourth, the internship should be so organized and administered that it emphasizes the beginning and the progressive increase of the assumption of personal responsibility for the care of the sick, the recognition and cultivation of the personal aspects of the treatment of patients, including family, social, financial, and morale factors, and the learning and acceptance from firsthand experience of the Principles of Medical Ethics and the code of professional conduct.

Fifth, that the service function of the intern, valuable as it is to the hospital, its staff, and its patients, should not be permitted to subordinate the educational purpose of the internship.

Sixth, that hospitals unable or unwilling for any reason to conduct internships meeting the educational standards of the Council on Medical Education and Hospitals in the spirit of the foregoing statements should not be encouraged to establish internships and such internships should not be approved. These hospitals should seek to meet their service needs by establishing house officer positions with adequate salary provisions.

Seventh, that all hospitals university connected and nonuniversity affiliated should be subject to these guiding principles.

The internship promises to continue to challenge medical educators, hospital administrators, and attending professional staff members in the years ahead. There is a widespread impression that the first year of hospital experience following graduation from medical school should be a well-planned rotating or mixed type of program rather than in any single field. There are those, however, who feel that a so-called straight internship if properly organized is satisfactory for the individual who clearly has decided his future area of interest. The value of any internship program will depend largely upon the basic planning underlying it, the continuity of integrated experience it affords, and the supervision it receives from responsible leadership. All medical schools have a "stake" in the internship and in its future as part of medical education.

GRADUATE EDUCATION TOWARD HIGHER DEGREES

Table 10, which portrays the over-all teaching responsibilities of medical schools in addition to the education of undergraduate medical students, indicates that many of the institutions are actively engaged in teaching and supervising graduate students specializing in various basic medical sciences and clinical areas. This is a highly important facet of medical school activity, for it is the students who elect to enter such work who largely constitute the reservoir of future teachers and investigators. Twenty-three medical schools in the United States report 772 physicians seeking M.S. degrees in 1954-1955, and 7 Canadian schools report 17 for the same period. Sixteen schools in the United States enrolled 182 physicians conducting graduate work toward the Ph.D. degree, and three Canadian institutions reported 10 such graduate physicians. Sixty-six schools in the United States reported 1,024, and seven Canadian institutions reported 38 graduate students other than physicians working toward master's degrees in basic medical sciences. Fifty-six schools in the United States reported 983, and nine in Canada reported 57 graduate students other than physicians enrolled in programs leading to Ph.D. degrees in the basic medical sciences.

GRADUATE TRAINING PROGRAMS DESIGNED FOR PROSPECTIVE GENERAL PRACTITIONERS

The medical school questionnaire this year included an inquiry in regard to the sponsorship of programs designed specifically for prospective general practitioners. Five institutions replied that internships were designed for this purpose, and eight indicated that they had aided in developing residency programs in general practice. The internships varied from one to two years in length and residencies from one to three years. Ten schools indicated that they were conducting courses, conferences, or clinics specifically designed for general practitioners. These programs were in addition to undergraduate preceptorships designed to offer medical students an opportunity to have a firsthand contact with the field of general or family practice.

Medical schools and hospitals have demonstrated magnificent leadership in developing excellent programs in graduate education for the specialty areas in recent years. On Sept. 1, 1954, there were 155 hospitals conducting approved graduate training programs in general practice. There were 404 assistant residents or residents participating in these programs. Many individuals among the medical profession, medical educators, and the general public believe that a very real challenge confronts medical education in this field. It is believed by many that there is need for a modern definition of what should constitute general or family practice as it confronts the young physician of today. If this can be accomplished there is need for cooperative planning on the part of medical schools, hospitals, and professional organizations in the formulation and implementation of graduate programs designed to furnish the background essential for the physician planning to enter this field. The broad challenges and needs for preparation in the field of general or family practice have, in the opinion of many thoughtful individuals, been allowed to go by default as those in the narrower specialty areas have received greater attention.

POSTGRADUATE MEDICAL EDUCATION

As has been pointed out in the recently completed Survey of Postgraduate Medical Education,[12] which was conducted by the American Medical Association under the auspices of the Council on Medical Education and Hospitals, postgraduate medical education has come to be looked upon as one of the three basic phases of medical education. However, the formalization of postgraduate education has proceeded slowly and somewhat haphazardly during the period when the undergraduate and graduate phases were making rapid strides. The survey clearly indicated that physicians have already recognized the importance of formal postgraduate study, as is evidenced by the fact that they prefer it above all other methods, except the reading of literature, for continuing education.

Approximately 70 undergraduate medical schools in the United States offered or participated in postgraduate medical courses during 1952-1953. The survey reports that they offered nearly 50,000 hours of postgraduate instruction, or about one-third of the nation's total. Physicians responding to the survey questionnaire ranked postgraduate courses offered by medical schools as highest in quality. An overwhelming majority of individuals interviewed during the course of the survey both inside and outside of medical schools expressed the belief that postgraduate medical education is a basic responsibility of the medical schools.

Increasing interest in and need for postgraduate medical educational opportunities will almost inevitably lead to continued greater responsibility for, and participation in, such activities on the part of the medical schools. Their leadership in cooperation with medical societies, hospitals, and the various agencies interested in postgraduate medical education is essential to the future orderly progress of continuing education in this field. Budget, faculty, and facilities for such activities present additional problems to medical administrators that can be evaluated only after careful analysis as to the area needs and type of postgraduate activities in which any given institution should engage. It would seem that the entire area of postgraduate medical education offers outstanding opportunities for regional and institutional cooperation, if maximum potentialities are to be achieved. Currently, in the absence of any effective regional or interinstitutional planning, much needless duplication of effort continues to take place.

The survey concludes that if duplication of effort is to be avoided there is need for the many and varied groups and organizations engaged in postgraduate medical education in any given area to combine their resources in a coordinated program. Neither physicians nor instructors respect state boundaries in their participation in postgraduate medical education and regional coordination would seem a logical approach.

Table 26 summarizes the listed offerings of postgraduate courses and their attendance over the 10 year period from 1945 to 1955. Courses have been divided into short (less than five days' duration), long (five days or more in duration), and miscellaneous (conferences, assemblies, study, circuit courses, and seminars). It is of more than passing interest to note that the drop in course offerings and in attendance in 1950-1951 was not sustained, and that 1954-1955 witnessed the largest recorded attendance to date (105,466), although total course offerings were fewer than in 1947-1948 or in 1951-1952. It should be clearly indicated that there is no way in which the exact total number of physicians in attendance at postgraduate courses can be determined. The total number of registrants includes many individuals who have attended two or more courses during the year. The increasing total registration, however, is indicative of the interest in this area of continuing education on the part of the medical profession.

Forty-nine of the medical schools in the United States and six of those in Canada conducted postgraduate courses during 1954-1955. They reported a total registration of 21,131 physicians enrolled for such courses.

Foreign Medical Schools and Students

FOREIGN STUDENTS STUDYING MEDICINE IN THE UNITED STATES

In 1954-1955, there were 379 foreign citizens (excluding Canadians) enrolled as undergraduate students in United States medical schools. All but 23 of the 81 approved schools had such students registered, with 104 in the entering class, 110 in the second year, 89 in the third year, and 76 in the fourth year. This represents a slight increase over last year in the number in the entering class and in total enrollment.

Our medical educational facilities make their greatest contribution to foreign students at the intern and residency level. The Institute of International Education, with some assistance from this Council, has recently completed a study of foreign physicians receiving training in United States hospitals. This study is one of three reported in a bulletin of the institute entitled "Open Doors." The results of this survey are also the subject of a recent publication by McCormack and Feraru.[13]

On the basis of returns from 90% of all hospitals approved for graduate training, it was found that there are currently slightly over 5,000 alien physicians serving in our hospitals as interns (approximately one-third) or residents (approximately two-thirds). This survey included only foreign physicians who were in this country for further study with commitments to return to their home countries at the completion of study.

Approximately one-quarter of these alien physicians come from the far eastern countries, one-quarter from Europe, one-quarter from Latin America, and the remaining quarter from other sections of the world.

This group of physicians is participating in intern and residency programs in 42 states, the District of Columbia, Puerto Rico, Hawaii, and the Canal Zone. It is interesting to note that almost 25% have positions in hospitals in New York State.

AMERICAN STUDENTS STUDYING MEDICINE IN OTHER COUNTRIES (EXCLUDING CANADA)

For a variety of causes it is not possible to obtain accurate information in regard to the number of American citizens studying medicine in other countries. Inquiries and other correspondence addressed to this Council suggest that there has been no significant decrease in the recent incidence of Americans seeking their education in medicine outside the United States. Since this appears to be a post-World War II phenomenon, the first of these students should now begin to appear for licensure examination.

Included in the information sent by the state licensing boards to this office is the place of birth and medical school attended of all candidates examined. These records were studied for the period 1950-1954 inclusive for new licentiates who were born in the United States and graduated from medical schools outside the United States and Canada. It is unfortunate that records from New York and Pennsylvania did not include this information, so that the data given below is for all states, territories, and possessions except New York and Pennsylvania. It is hoped that in the future similar data can be made complete by the addition of information from these two states.

During the five year period studied, 99 initial licenses were granted by 18 states, the District of Columbia, Puerto Rico, and the Canal Zone to physicians born in the United States who were graduates of medical schools outside the United States or Canada. Four states, California, New Jersey, Ohio, and Connecticut, granted 64% of all such licenses.

Physicians in this group graduated from medical schools located in 20 different countries, but almost half were graduates of medical schools in Italy or Switzerland. Initial licenses were granted to 15 such physicians in 1950, 10 in 1951, 15 in 1952, 22 in 1953 and 37 in 1954. These figures are in keeping with the belief that we are now just beginning to note the impact of American citizens who studied medicine abroad.

It should be emphasized again that the data given above depicts initial licenses granted to individuals born in the United States who graduated from medical schools outside the United States and Canada. Information on initial licenses granted to such individuals by the states of New York and Pennsylvania is not included.

FOREIGN MEDICAL SCHOOLS

In February, 1950, the Council on Medical Education and Hospitals of the American Medical Association and the Executive Council of the Association of American Medical Colleges first published a list of foreign medical schools whose graduates they recommended for consideration on the same basis as graduates of approved medical schools in the United States. This recommendation is intended only for those students who successfully complete a course of study identical in all respects with that necessary to be eligible for licensure in the country in which the school is located. This list is intended as a guide for institutions and organizations in this country that deal with foreign medical graduates and as an aid to students who plan to study medicine abroad. It appears in this report as table 27.

It is to be emphasized that it is not now and never has been the policy of the organizations sponsoring this list to consider that action listing a foreign medical school is equivalent to granting approval to medical schools in the United States and Canada. Neither is it intended that there be any inference of disapproval of those foreign medical schools not listed. The list is intended only as a guide to state licensing boards, hospitals, and similar groups with the clear understanding of the Council on Medical Education and Hospitals and the Executive Council of the Association of American Medical Colleges that the ultimate responsibility for evaluating medical credentials and qualifications of foreign-trained physicians, whether graduates of listed or nonlisted schools, rests with those other organizations and not with the sponsors of the list.

Somewhat more than a year ago, a cooperating committee on evaluation of graduates of foreign medical schools was formed with participating representatives from the Council on Medical Education and Hospitals,

TABLE 27.—*Foreign Medical Schools*

List Prepared by the Council on Medical Education and Hospitals of the American Medical Association and the Executive Council of the Association of American Medical Colleges

On the basis of information presently available, the Council on Medical Education and Hospitals of the American Medical Association and the Executive Council of the Association of American Medical Colleges are of the opinion that medical institutions and medical organizations in the United States would be justified in considering current and past graduates of the following foreign medical schools on the same basis that they consider graduates of approved medical schools in the United States. This recommendation is intended only for those students who successfully complete a course of study identical in all respects with that necessary to be eligible for licensure in the country in which the school is located. *Because this list is acknowledged to be a tentative one, the position of the councils with respect to schools not named in the list is that they neither approve nor disapprove them.*

Belgium

Free University of Brussels Faculty of Medicine
(Université Libre de Bruxelles Faculté de Médecine)
Catholic University of Louvain Faculty of Medicine
(Université Catholique de Louvain Faculté de Médecine, or
Katholieke Universiteit te Leuven)
University of Ghent Faculty of Medicine
(Universiteit te Gent Faculteit der Geneeskunde, or
Université de Gand Faculté de Médecine)
University of Liège Faculty of Medicine
(Université de Liège Faculté de Médecine)

Brazil

University of São Paulo Faculty of Medicine
(Universidade de São Paulo Faculdade de Medicina)

China

Peiping Union Medical College

This recommendation applies to all those graduates who were granted the degree of Doctor of Medicine from the date when the first degrees were conferred in 1924 until and including the class of 1943. The education of students in the last class, that of 1943, was interrupted by World War II; therefore, some students finally completed their studies as late as 1949. However, their diplomas were issued as of the class of 1943. Following the communist conquest of China, the name of this school was changed to the China Union Medical College. The recommendation does not apply to this school.

Denmark

University of Copenhagen Faculty of Medicine
(Kobenhavns Universitet Laegevidenskabelige Fakultet)

Finland

University of Helsinki Faculty of Medicine
(Helsingfors Universitet Medicinska Fakulteten)
Medical Faculty Turku University
(Turun Yliopiston Laaketieteelinen Tiedekunta)

Lebanon

American University of Beirut School of Medicine

Netherlands

University of Amsterdam Faculty of Medicine
(Universiteit van Amsterdam Geneeskunde Faculteit)
State University of Groningen Faculty of Medicine
(Rijks-Universiteit te Groningen Geneeskunde Faculteit)
State University of Leiden Faculty of Medicine
(Rijks-Universiteit te Leiden Faculteit der Geneeskunde)
State University of Utrecht Faculty of Medicine
(Rijks-Universiteit te Utrecht Faculteit der Geneeskunde)

The Doctoral Examen that is given at the end of the theoretical part of the study of medicine does not confer the degree of Doctor nor the right to practice medicine. The Arts Examen that is given following the completion of an additional two years of practical work in hospitals confers the title of Doctor and also the right to practice medicine.

Norway

University of Oslo Faculty of Medicine
(Kongelige Frederiks Universitet Medisinske Fakultet)

Sweden

Royal Charles University Medical Faculty, Lund
(Kungl. Karolinska Universitetet Medicinska Fakulteten)
Charles Medico-Surgical Institute, Stockholm
(Karolinska Mediko-Kirurgiska Institutet)
Royal University of Uppsala Medical Faculty
(Kungl. Universitetet i Uppsala Medicinska Fakulteten)

Switzerland

University of Basel Faculty of Medicine
(Universität Basel Medizinische Fakultät)
University of Bern Faculty of Medicine
(Universität Bern Medizinische Fakultät)
University of Geneva Faculty of Medicine
(Université de Genève Faculté de Médecine)
University of Lausanne Faculty of Medicine
(Université de Lausanne Faculté de Mèdecine)
University of Zurich Faculty of Medicine
(Universität Zurich Medizinische Fakultät)

The recommendation with respect to the following medical schools in Switzerland applies only to those graduates of Swiss medical schools who hold the Swiss-Federal Diploma issued by the Federal Department of the Interior (Eidgendoissisches Department Des Innern, Département Féderal de L'Intérieur) and obtainable only by Swiss citizens who hold the Certificate of Medical Studies (Akademische Zeugnis, Certificat d'Études Médicales) or who hold one of the following certificates which the Swiss Universities issue to those, not citizens of Switzerland, who complete a course of study and pass examinations equivalent to those taken by Swiss citizens in qualifying for the Swiss Federal Diploma:

University of Basel—Academic Certificate on passing the medical examination for physicians (Akademische Zeugnis über die bestandene Fachprufung für Ärzte).

University of Bern—Medical diploma on passing examination for medicine (Aerztliches Fakultats diplom über die bestandene Fachprufung für Ärzte).

University of Geneva and University of Lausanne—Certificate of Medical Studies (Certificat d'Études Médicales).

University of Zurich—Medical diploma for Foreigners (Medizinisches Diplom für Ausländer).

United Kingdom

England

University of Birmingham Faculty of Medicine
University of Bristol Faculty of Medicine
University of Cambridge Faculty of Medicine
University of Durham Medical School, Newcastle-upon-Tyne
University of Leeds Faculty of Medicine
University of Liverpool Faculty of Medicine
University of London*
University of Manchester Faculty of Medicine
University of Oxford Faculty of Medicine
University of Sheffield Faculty of Medicine

Northern Ireland

Queen's University of Belfast Faculty of Medicine

Scotland

University of Aberdeen Faculty of Medicine
University of Edinburgh Faculty of Medicine
University of Glasgow Faculty of Medicine
University of St. Andrews Medical School, St. Andrews and Dundee

Wales

Welch National School of Medicine, University of Wales, Cardiff

The recommendation applies only to those physicians trained in the United Kingdom who hold medical degrees from the universities listed. The recommendation does not apply to those physicians who received their medical training at these universities or their affiliated hospital medical schools but who obtained their qualifications through the examinations of the licensing corporations of the United Kingdom. It must be observed, however, that registration in the United Kingdom is granted equally to physicians holding the diplomas of the licensing corporations and to physicians holding university medical degrees.

---

* Work for the medical degree of the University of London is offered at the following hospital medical schools:

Charing Cross Hospital Medical School
Guy's Hospital Medical School
King's College Hospital Medical School
London Hospital Medical School
Middlesex Hospital Medical School
Royal Free Hospital School of Medicine
St. Bartholomew's Hospital Medical College
St. George's Hospital Medical School
St. Mary's Hospital Medical School
St. Thomas' Hospital Medical School
University College Hospital Medical School
Westminster Hospital Medical School

the Federation of State Medical Boards, the Association of American Medical Colleges and the American Hospital Association. This committee has not been able to formulate as yet a final program that would provide an equitable and adequate method of evaluating graduates of foreign medical schools. Certain progress in this direction has been made, however, and it is the hope and belief of the cooperating committee that it will be able to devise a mechanism for satisfactorily measuring the individual physician rather than attempting to measure educational programs in foreign medical schools. It is presumed that with the development and implementation of an effective program for evaluating foreign graduates, there will no longer be a need for the listing of foreign medical schools.

Technical Schools

The present report on the technical schools approved by the Council on Medical Education and Hospitals includes background material and the present status of educational programs for medical technologists, x-ray technicians, physical therapists, occupational therapists, medical record librarians, and medical record technicians. The lists of approved technical schools are not included in the present issue but have been revised and published in a separate supplement that will be distributed to hospitals, medical schools, approved technical schools, secretaries of state medical associations, editors of state medical journals, state boards of medical examiners, national and state hospital associations, state boards of nursing examiners, state health officers, medical departments of the federal government, allied technical associations, and other agencies. Copies are also available to individual physicians and other subscribers to THE JOURNAL and may be obtained from the Council on Medical Education and Hospitals of the American Medical Association. Copies of the essentials of an acceptable school for establishing educational programs in these important paramedical fields, in which shortages are acute, are available from the Council to those interested in initiating new schools.

SCHOOLS FOR MEDICAL TECHNOLOGISTS

Background.—In 1928 the American Society of Clinical Pathologists established its board of registry of medical technologists in an effort to elevate educational standards for medical technologists. Realizing the need for school inspections, the society requested the Council on Medical Education and Hospitals of the American Medical Association to aid in the study of training programs in 1933. Essentials of an acceptable school were formulated by the Council with the cooperation of the society and ratified by the House of Delegates of the American Medical Association in May, 1936. The first list of 96 schools approved by the Council was published in THE JOURNAL on Aug. 29, 1936.

In its continuous effort to assist hospitals in the development of training programs, the Council has received the full cooperation of the American Society of Clinical Pathologists, and the board of schools of medical technology and board of registry of the society. The board of schools was established by the society in 1949 to serve in an advisory capacity to the Council in matters relating to standards and the evaluation of educational programs. Revisions of the standards occurred in 1941, 1943, 1947, 1949, and 1953.

The board of schools assists the Council in the evaluation of new applications and annual reevaluations of approved schools. An inspection program is carried out by regional inspectors appointed by the board of schools. These pathologists survey all new schools and, in addition, periodically revisit approved schools. The recommendations of the board on new applications and existing schools of medical technology are submitted to the Council for its consideration.

Present Status.—There are 595 schools presently approved by the Council on Medical Education and Hospitals, or a percentage increase of almost 4% over the 575 approved as of May 15, 1954. This is a net increase of 20 training programs which represents 46 newly approved schools, 23 that have been discontinued, 1 disapproved school, and 2 affiliating hospitals previously tabulated as separately approved schools. On the basis of 1954 annual reports, student enrollment has risen almost 5% to 2,384, as compared with the 2,275 reported in 1953.

Reflecting the concerted recruitment efforts of the College of American Pathologists, American Society of Clinical Pathologists, and American Society of Medical Technologists, the occupancy rate for 1954 is 51% in the 595 educational programs, which have a total training capacity of 4,613 students. Unfortunately, the number of graduates continues to decline. There were 2,063 graduates in 1952, 1,971 in 1953, and 1,956 in 1954. It should be noted that the expected increases in the number of graduates and the 1955 enrollment expected in existing and newly approved schools are not represented in the above tabulations, whereas the increase in current student capacity is included.

The admission requirement to an approved school of medical technology is two years of college education, including certain required courses, in a college or university accredited by a recognized standardizing association. Slightly over 82%, or 489 training programs, base admission on this minimum requirement; 73 (12%) require three years of preclinical college education; and 33, or 6%, a degree for admission.

Collegiate affiliations are encouraged, since they assist in the development of well-organized training programs suitably integrated with the college curriculum, as well as serving as a continuing source of students. A total of 374 hospital schools (63%) have established college or university affiliations. College credit is granted for training received in the hospital training program in 57%, or 337 schools, and a degree is available upon completion of a combined three years of college education followed by one year of hospital training in 54%, or 322 schools. While the preparatory collegiate education is longer in duration, it is the hospital course that is directly concerned with the training of medical technologists. The hospital, therefore, should assume full responsibility for the required 12 month course.

The minimum duration of the hospital course, as specified in the essentials, is 12 months. There are now

523 schools, or 88%, conforming to this requirement, of which 21 schools offer, in addition to the 12 month course, longer training programs. The remaining 72 schools (12%) offer programs of from 12½ to 36 months in duration. Tuition is required by 163 (27%) of the schools and 213 (36%) pay a stipend to students.

Pennsylvania has 46 schools, Ohio 43, Illinois and Michigan 33 each, New York 32, and Texas 31. Pennsylvania schools report a student capacity of 417 with a student occupancy of 54%; Ohio 366, 37% occupancy; Texas 292, 38% occupancy; Michigan 284, 42% occupancy; New York 220, 55% occupancy; and Illinois 219, with a 53% student occupancy. All states, the District of Columbia, the Canal Zone, Hawaii, and Puerto Rico have approved schools.

Application for approval of a school for the training of medical technologists should be made to the Council on Medical Education and Hospitals of the American Medical Association, 535 N. Dearborn St., Chicago 10. Forms will be supplied for this purpose on request and should be completed by the director of the laboratory requesting this approval. Inquiries regarding the registration of qualified medical technologists should be addressed to the Board of Registry of Medical Technologists, P. O. Box 1209, Muncie, Ind.

SCHOOLS FOR X-RAY TECHNICIANS

Background.—Prior to 1944, the approval of these schools had been carried on as a function of the American Registry of X-Ray Technicians. In 1943, the Council on Medical Education and Hospitals of the American Medical Association undertook the evaluation of educational programs for x-ray technicians at the request of the registry, which is sponsored by the American College of Radiology and the American Society of X-Ray Technicians. With the assistance of the college and the registry, standards were developed and adopted by the House of Delegates of the American Medical Association in June, 1944.

Since that time the Council has been increasingly and ably assisted by the American College of Radiology, the American Registry of X-Ray Technicians, and the American Society of X-Ray Technicians. Schools making application for approval are surveyed by state and regional councilors appointed by the American College of Radiology. Approved schools are also periodically resurveyed by radiologists appointed by the College. All data are reviewed by the advisory committee to the American Society of X-Ray Technicians of the American College of Radiology and recommendations submitted to the Council for consideration.

During the past year, revisions of the 1944 standards have been developed with the advisory groups. These revisions, which incorporate a suggested basic curriculum previously approved by the college, registry, and society, will be submitted to the House of Delegates of the American Medical Association for its consideration in December.

Present Status.—At present there are 422 schools approved by the Council on Medical Education and Hospitals for training x-ray technicians. This represents a net increase of 53 schools, or an increase of 14% over last year; there were 58 newly approved schools, 4 discontinued and 1 disapproved school. There has been a 377% increase in the number of approved schools since the first published list of 112 in 1945. Enrollment has increased 517, or 25%, to a total of 2,613 students during the last year in which total training capacity has risen to 3,184 from 2,583, or an increase of 23%. The number of graduates in 1954 was 1,523, as compared with 1,259 in 1953, which is a 21% increase.

The minimum admission requirement is high school graduation or passing a college entrance examination. A total of 400 schools (95%) admit students directly out of high school, 13 schools (3%) require one year of college, 8 schools (almost 2%) require two years of college, and 1 school accepts only R.N.'s. Of the above 422 schools, 6 will accept an applicant with either an R.N. or one to two years of college, 4 an R.N. or high school graduation, and, as noted, 1 school accepts R. N.'s only.

The length of training in 195 schools (46%) is 24 months, 12 months in 158 (38%), 18 months in 38, or 9%, a range of 12 to 24 months in 9 (2%), and a range of 14 months to 4 years in the remaining 22 (5%). Tuition is required by 37% of approved schools, and 57% pay students a stipend. There are collegiate affiliations established with 148 schools (35%). College credit is granted for training satisfactorily completed in the hospital training program in 13%, or 53 schools.

There are 38 approved schools in Illinois, 30 in Pennsylvania, 28 in Ohio, 23 in Texas, 21 in California, 18 each in Michigan, Missouri, and New York, 16 in Wisconsin, and 14 or fewer in all but one of the remaining states, the District of Columbia, and Hawaii. One state does not have a school.

Applications for approval of schools of x-ray technology should be submitted to the Council on Medical Education and Hospitals of the American Medical Association, 535 N. Dearborn St., Chicago 10. Inquiries regarding registration of qualified x-ray technicians should be addressed to the American Registry of X-Ray Technicians, Metropolitan Building, Minneapolis 1.

SCHOOLS FOR PHYSICAL THERAPISTS

Background.—From 1928 to 1936 the approval of educational programs in this field was carried out by the American Physical Therapy Association. On request of that association, the Council developed standards that were adopted by the House of Delegates and were published with the first list of 13 approved schools in 1936. The Council, in cooperation with its advisory groups, the Council on Physical Medicine and Rehabilitation of the American Medical Association and the American Physical Therapy Association, has periodically submitted revised standards to the House of Delegates, which were adopted in 1943 and 1949. As a result of over three years of intensive discussion and study, a current revision of standards for educational programs will be submitted to the House in December for its consideration.

Applications of new schools are reviewed by the advisory groups, surveys are conducted by the Council staff, and recommendatory action is submitted to the Council for action. More thorough periodic evaluation of approved schools is under study.

Present Status.—There are, at present, 35 schools approved by the Council for training physical therapists. This represents an increase of two new schools, in that three affiliating army hospitals were previously tabulated as separate training programs. The training capacity of the senior class in degree and certificate programs is 941 students, as compared with 898 in 1953 and 842 in 1952. The schools reported 1954 senior class enrollment as 690, or a 73% occupancy. As a result of intensive recruitment, enrollment in the preparatory years of training is also increasing. The number of graduates from the degree and certificate programs for the past five years has steadily risen except for the year 1952. There were 490 in 1950, 591 in 1951, 582 in 1952, 591 in 1953, and 609 graduates in 1954.

Certificate and/or degree recognition in physical therapy is available depending upon the students' preparatory education prior to entering the professional curriculum specified in the essentials of an acceptable school. Most schools have both certificate and degree programs, although some offer only one course.

Certificate programs offered in 30 schools vary in length from 12 months to 34 months. The certificate educational program is 12 months in 20 schools and varies from 14 to 34 months in the remaining 10. Students may qualify for entrance to many of the approved schools in several ways. Three years of college education is required by 16 schools, graduation from a nationally accredited school of nursing of at least three years' duration to include certain prerequisite courses is specified by 16, 12 require four years, 5 specify two years of college prior to admission, and 9 will accept qualified graduates of schools of physical education.

The entrance requirement for 18 degree programs of four years' duration is high school graduation. In the remaining 10 degree programs, which are of shorter duration, entrance requirements are specified as three years of college by 6, two years by 3, and four years of college by 1 of the schools. The tuition in all teaching centers closely parallels college fees. Most courses begin in February or the early fall.

Applications for approval should be made to the Council on Medical Education and Hospitals of the American Medical Association, 535 N. Dearborn St., Chicago 10. Forms will be supplied for this purpose on request. They should be completed by the administrator of the institution requesting this approval. Inquiries regarding registration of qualified therapists should be addressed to the American Registry of Physical Therapists, 30 N. Michigan Ave., Chicago 2.

SCHOOLS FOR OCCUPATIONAL THERAPISTS

Background.—In 1933 the American Occupational Therapy Association requested the House of Delegates of the American Medical Association to undertake a survey of educational programs for occupational therapists. Under instruction from the Board of Trustees, the Council on Medical Education and Hospitals developed standards and surveyed existing schools. The Essentials of an Acceptable School of Occupational Therapy were first published in The Journal, May 4, 1935. The first list of six approved schools appeared in 1938. In cooperation with the advisory groups in occupational therapy, the Council on Physical Medicine and Rehabilitation of the American Medical Association, and the American Occupational Therapy Association, the essentials were revised in 1938 and 1949. New applications are reviewed by the advisory groups, surveys are conducted by the staff, and recommendatory action is submitted to the Council on Medical Education and Hospitals for action. Increased attention is being given to procedures for more frequent periodic reevaluation of existing educational programs.

Present Status.—There are currently 29 schools approved by the Council for training occupational therapists. This represents a net increase of 2 new schools since the May 15, 1954, list of 31 schools separately tabulated, 4 Army hospitals affiliating with one army school. There will be no students accepted into the Army occupational therapy course for the fiscal year 1956, since the course has been put on a stand-by basis.

There has been an increase in student capacity of 61 in 1954 to a total capacity of 960. The enrollment in the senior class of degree and in certificate and advance standing courses is 568 students as compared with 602 for 1953. It should be noted that the schools reported 493 students, not included in the above enrollment, as engaged in the clinical training phase of courses. For the past five years there has been a continuous increase in the number of graduates as follows: 377 in 1950, 418 in 1951, 441 in 1952, 472 in 1953, and 489 in 1954. This represents a percentage increase of 30% in the past five years.

Both certificate and degree recognition are available in occupational therapy depending upon the type and integration of preparatory training prior to entering the professional curriculum. Certificate programs, generally of 18 to 24 months in length, are offered by 22 schools, of which 20 specify a degree prior to admission and 2 accept qualified applicants with either a degree or an R.N. Educational programs of four to five years' duration that lead to a degree are available in 24 schools that admit students directly from high school. Two schools require two years of college prior to admission to degree courses of slightly over two years' duration. Tuition varies in accord with university fees. The majority of courses begin in February and September.

Application for the approval of a school of occupational therapy should be made to the Council on Medical Education and Hospitals of the American Medical Association, 535 N. Dearborn St., Chicago 10. Forms will be supplied for this purpose on request. They should be completed by the administrator of the institution requesting approval. Inquiries regarding the registration of qualified therapists should be addressed to the American Occupational Therapy Association, 33 W. 42nd St., New York 18.

SCHOOLS FOR MEDICAL RECORD LIBRARIANS

Background.—In 1942 the American Association of Medical Record Librarians requested the American Medical Association to evaluate educational programs in medical record library science. The Council formulated standards that were adopted by the House of Delegates of the American Medical Association in June, 1943. Subsequent revisions in standards were made in 1945 and 1949. The first list of 10 approved schools was published in 1944.

Working in close collaboration with the American Association of Medical Record Librarians, its committee on education and registration, and its recently appointed education director, training programs and new applications are reviewed by the Council, periodic surveys are conducted, and recommendatory action is submitted to the Council for action on new and existing schools.

Present Status.—At the present time there are 25 schools approved by the Council for training medical record librarians. This represents a net increase of one school, including two newly approved schools and one school that has been discontinued since 1953. Eighteen approved schools reported a 1954 enrollment of 115, which is an increase of 9 students over the 106 training in the 18 schools that had students in 1953. The number of graduates has progressively increased during the past three years. Graduates for the past five years were as follows: 83 in 1950, 58 in 1951, 92 in 1952, 99 in 1953, and 114 in 1954, or an increase of 38 per cent in this period. A student capacity of 231 was reported for 1954 as compared with 218 in 1953.

Depending upon the students' previous education, both degree and certificate recognition are available following satisfactory completion of the required training program in medical record library science. Of 18 certificate programs that are one year in duration, 13 require either two years of college education or an R.N. for admission, 1 accepts only students with two years of college training, and 4 require a degree. Six schools offer a four year educational program which leads to a degree and admit students directly out of high school. Three schools have a degree program of 12 months' duration with an admission requirement of three years' preparatory college education. Since two schools offer both degree and certificate courses, there are 18 certificate and 9 degree programs available in the total of 25 approved schools. Fifteen schools maintain college or university affiliations.

The beginning dates for courses are predominately in September, several begin in the winter, and a few in June or July. Tuition ranges from $135 to $600, and one school requires none.

Application for approval should be made to the Council on Medical Education and Hospitals of the American Medical Association, 535 N. Dearborn St., Chicago 10. Inquiries regarding the registration of qualified medical record librarians should be addressed to the American Association of Medical Record Librarians, 510 N. Dearborn St., Chicago 10.

SCHOOLS FOR MEDICAL RECORD TECHNICIANS

Background.—In view of the continuing acute shortage of trained personnel in medical record library science, the American Association of Medical Record Librarians recommended that consideration be given to the establishment of additional training programs for students directly out of high school. In cooperation with the Committee on Education and Registration of the American Association of Medical Record Librarians, the Council developed standards which were approved by the House of Delegates of the American Medical Association in December, 1953. These standards are prepared for the training of the medical record technician who, working under the supervision of a qualified medical record librarian or a medical record committee, performs the technical tasks associated with the maintenance and custody of medical records.

As in the case of schools for medical record librarians, the Council evaluates educational programs and new applications and surveys schools in close collaboration with the American Association of Medical Record Librarians. The training of medical record technicians should be conducted in acceptable general hospitals having a minimum of 4,000 annual admissions. These admissions should include an adequate distribution of patients in the various clinical services commonly found in general hospitals. Candidates for admission to an approved school should be proficient in typing and preferably also in shorthand. They should have completed the requirements for high school graduation or should have passed a college entrance examination for admission to an accredited college or university. The minimum length of training is nine months and should include theoretical instruction in anatomy, medical terminology, and medical records, with additional practical training in admitting and discharge procedures, indexing, preparation of reports, and other activities associated with the medical record department.

Present Status.—There are seven schools approved by the Council for training medical record technicians. These schools report a training capacity for 46 students with an enrollment of 28 in 1954. Qualified high school graduates are accepted for courses of from 9 to 12 months' duration. There were 17 graduates reported in 1954.

Application for approval should be made to the Council on Medical Education and Hospitals of the American Medical Association, 535 N. Dearborn St., Chicago 10. Special forms will be supplied for this purpose, and when the required information has been received, the proposed training program will be reviewed in collaboration with the Committee on Education and Registration of the American Association of Medical Record Librarians. The institutions applying for Council approval will, in all instances, receive full information and every possible assistance in the planning and development of training programs in accordance with present standards. Inquiries regarding the registration of qualified medical record personnel should be addressed to the American Association of Medical Record Librarians, 510 N. Dearborn St., Chicago 10.

MEDICAL EDUCATION IN THE UNITED STATES AND CANADA, 1954-1955

This issue of THE JOURNAL carries the 55th Annual Report on Medical Education in the United States and Canada prepared by the Council on Medical Education and Hospitals of the American Medical Association. Its objective is to inform the profession and all others interested of the current status, developments, and trends in this important area of education. Administrative officials of medical schools and their parent universities and representatives of other agencies have been most cooperative in the submission of the current data and information essential in the compilation of a report of this nature, and for this assistance the Council is deeply grateful.

Analysis of the statistical data and textual information reveals that 1954-1955 has continued to be a year of steady progress in the field of medical education. The University of California at Los Angeles graduated its first class of physicians in June, 1955. Thus there are now 75 approved four year medical schools and 6 schools of basic medical science in the United States. Canada has 11 approved four year medical schools and one school of basic medical science. In 1956 the University of Miami will graduate its first class. The University of Missouri and the University of Mississippi will initiate the instruction of their first third year classes in 1956 in their process of conversion from a two year basic science to a four year program. Albert Einstein College of Medicine has admitted its first entering class for the 1955-1956 academic session. Current plans envisage the admission of the first students at Seton Hall College of Medicine and the University of Florida for the 1956-1957 academic session.

Total enrollment in medical schools in the United States during the 1954-1955 academic year was 28,583, and 6,977 physicians were graduated. This is an all-time record, both for total enrollment and for physicians graduated. It is anticipated that there will be a slight drop in the number of graduates in 1956 and that thereafter, with the completion of the medical school programs currently under development, there will be a steady augmentation of the number of graduates through 1960. It is not possible to accurately estimate the actual number of potential graduates at that time, as the total may be increased by larger enrollments in existing medical schools in addition to those of the newly developing schools.

The general information tables on approved medical schools in the United States and Canada have been made more comprehensive in this report and have made it possible to eliminate several pages of material formerly devoted to short summary sketches on each institution.

Curriculum studies and readjustments are constantly being conducted by the medical schools in efforts to meet the continuing challenge that is presented by the rapid advances in knowledge and the readjustments of emphasis that such information necessitates. On every hand there is evidence of stimulating educational experimentation in the constant effort to afford the best possible background for the young physician. The Council staff can find no institution in the field of undergraduate medical education in the United States and Canada where there is not tangible evidence of continuing effort to achieve the best possible objectives within the limits of the personnel, facilities, and finances of each institution.

There has been a modest improvement in medical school financing as indicated by the projected budgets for 1955-1956; however, the basic "hard money" sources have increased relatively little, while funds available from grants-in-aid for special teaching projects and research have materially increased. It is of considerable interest to all concerned with and interested in the activities of medical schools that such outside grants-in-aid approximate two-thirds of the sum budgeted for basic medical school activities. It is furthermore of interest to note that, except for the facilities and part of the personnel financed by the basic medical school budgets, approximately 95% of the support of the important research that is now conducted by the medical schools is made possible by and is dependent on such grants. Efforts have been made in this report to highlight the importance of this "medical school—granting agency" partnership that has developed in recent years and that has been largely responsible for the greatly augmented teaching and research activities that the schools have been able to conduct.

During recent years, programs of regional cooperation in the field of higher education, beginning with the development of the Southern Regional Education Board, have demonstrated the potentialities of interstate arrangements. These programs to date have used the facilities of both private and government-supported schools in the effort to improve educational opportunities and at the same time to reduce the need for duplication of costly professional educational institutions in areas that could finance them only under great difficulty. The Western Interstate Compact for Higher Education is now under way, and the basis for a New England regional program has been established. It is to be hoped that the further development of interstate cooperation of this type will continue to give full consideration to the role of both private and government-supported institutions, as it appears to be an exceedingly logical and workable means of approach to meeting needs for opportunities in higher education as well as allowing fair distribution of its cost factors.

This report includes the basic table of a study that has been conducted by the Bureau of Economic Research of the American Medical Association in regard to what happens to medical school graduates. In the relatively near future, the Bureau will issue a report to the medical schools that will give each institution a comprehensive picture of the activities of its graduates and their distribution. It will afford comparative study of the areas of activity into which the graduates of each of the schools have entered. The initial study will represent data for the schools through April, 1950, and it is planned that supplementary data will be furnished in the course of the next two years.

Along with the many evidences of continued progress, the field of medical education faces many challenging problems. Improved financing for more adequate and modernized facilities in some institutions and for faculty remuneration continues to be an important problem. This area of challenge includes clarification of the financing of clinical faculty personnel, questions concerning the institutional practice of medicine, and relationship between medical school faculties and physicians in private practice in areas where schools are located. Faculty recruitment constantly presents challenging problems. Student recruitment is of equal concern. It is to be hoped that the downward trend in number of applicants for admission to the study of medicine has reached its limit and that there will be an increase in qualified applicants in the future. Curriculum readjustments will be a continuing challenge in efforts to meet the constantly changing needs. Each medical school faces the eternal need of maintaining a proper and reasonable balance between its activities in teaching and research. There is no common equation that is applicable in the determination of what this balance should be, and each institution must satisfy its requirements in light of the facilities, faculty personnel, objectives, and resources available to it. Finally, the increasing responsibilities of medical schools in graduate and postgraduate medical education necessitate constant evaluation and reorientation of over-all administrative and teaching and research activities as well as readjustments of facilities, personnel, and financing.

PARTNERSHIP IN MEDICAL TEACHING AND RESEARCH

In the information in this issue of THE JOURNAL in regard to the projected financing of medical education and research during 1955-1956 it will be observed that grants for research and teaching from outside sources will make funds available for these activities equivalent to about two-thirds of the amount projected for basic operational budgets derived from government appropriations, endowment, tuition, general university appropriations, and gifts. Although the medical schools do finance from their basic budgets some of the facilities, equipment, general administrative, and some of the personnel factors involved in these special activities, only 23 of the 81 medical schools in the United States report a total of slightly over $1,500,000 allocated to research from their basic operational budgets. In other words, nearly 40 times as much support for research and special teaching projects is anticipated from outside sources as is to be derived from basic operational budget allocations.

For many years it has been recognized by medical educators that education and research are full partners in the modern setting of a dynamic medical school. New knowledge is accumulating with almost unbelievable rapidity. New problems as well as many older still unsolved ones constantly confront those who teach and practice medicine. The concept of a progressive medical educational institution can no longer be built around the motif of teaching alone, for the staff and curriculum of such an institution would be obsolete almost from the beginning. Good teachers in medicine are persons who are not content with passing on known information and guidance as to its use. They are individuals who are concerned with and stimulated by the constant challenges to solve some of these problems. It is this interest in the solution of problems that, in addition to ability and background preparation, constitutes the backbone of the research instinct. One of the greatest attractions in the field of academic medicine is the opportunity to work in the field of investigation along with the activities involved in teaching students. The end-products of acquisitions to knowledge are not the only inherent values of the research conducted in the medical school environment. One of the important by-products of an environment in which both active teaching and research are taking place is the opportunity offered to medical students to become fully aware of and eventually possessed with the research attitude in its application to all aspects of the practice of medicine.

The present-day development of research in association with teaching presents many problems to medical administrators and teachers. The primary function of medical schools as educational institutions must constantly be maintained in the forefront. Research activities should supplement and enhance the teaching in an institution and never be permitted to overshadow or interfere with the basic needs for sound medical education. The appropriate balance of activities in the two areas is difficult to determine and is a local challenge for each institution to solve in the best interests of both teaching and research.

The support of the activities in teaching and research has in recent years become a partnership between institutions that maintain the basic educational programs and the outside agencies that allocate funds for research and special teaching programs. The importance of this partnership in the maintenance of this dual responsibility should be given full recognition. Many foundations and other organizations have played important roles over the years in underwriting the financing of important experimental educational programs as well as research activities. Among them are such organizations as the Rockefeller Foundation, the Commonwealth Fund, the Carnegie Corporation, John and Mary R. Markle Foundation, the W. K. Kellogg Foundation, the Kresge Foundation, the M. D. Anderson Foundation, the National Foundation for Infantile Paralysis, the American Cancer Society, the American Heart Association, and many other organizations in the fields of mental health, arthritis, crippled children, and various categories of the exceptional child. Pharmaceutical organizations and drug manufacturers have been important contributors to both research and continuing education programs. The Public Health Service and its National Institutes of Health as well as other federal agencies have in recent years constituted the group of organizations allocating the greatest support to research and to the development of special teaching projects.

In any evaluation of the support of the activities conducted in the environment of the medical schools today it is important that full recognition be given to all of the factors that play such important roles in the education of physicians and in the advance of medical knowledge. Without the interest and financial assistance afforded by these many organizations and agencies the dual activities of teaching and research could not have attained their present high development.

BACKGROUND FOR GENERAL OR FAMILY PRACTICE AND SPECIALIZATION

Occasionally the impression is gained that there are some who believe that the basic education and training offered to medical students and young physicians who contemplate entering the field of general or family practice should be something different, less thorough and less exacting than is needed by those who plan to specialize. The discarding of any such outmoded and erroneous concept of a double standard of excellence in basic medical education and training or in medical care is long overdue. The medical profession itself is dedicated to the concept of the best possible medical care for the American public. This necessitates adherence to a single standard of excellence in basic undergraduate and graduate education and training for all medical students and physicians regardless of the field of medical practice that they eventually choose to follow. The cultivation and teaching of medicine on a strictly scientific basis accompanied by wise indoctrination in the art of practice is the only sound professional education to offer all persons planning to dedicate their future to any phase of the practice of medicine. To achieve this end there can be no concept of double standards.

Events occurring in the first half of the 20th century have profoundly changed the practice of medicine and the educational background essential in preparation for its pursuit. Knowledge of scientific information applicable to all areas of medical practice has accumulated with almost bewildering rapidity. At the turn of the century a medical diploma was almost an open door to any and all facets of the medical practice of that period. With the currently available knowledge applicable to medicine no single individual can be equally effective in all areas of practice. Specialization has been a natural and necessary accompaniment of this vast accumulation of applicable scientific knowledge. It is a recognized essential part of the practice of medicine today and will be a permanent aspect of the medicine of the future. To be of maximum effectiveness it must be cooperative in nature, for man and his medical problems must be evaluated as a whole and not in isolated segments.

The need for high standards of preparation for the practice of any specialty in medicine has long been recognized. Excellent programs of graduate and postgraduate medical education have been developed by the various specialty boards in their efforts to assure that those whom they certify can render the best possible care to the American public they will serve. On the other hand, the planning and development of genuinely adequate programs of graduate education for those who choose to follow the field of general or family practice has not generally received such meticulous attention on the part of medical educators.

In view of the broad and comprehensive challenge confronting any physician who enters the field of general or family practice today, it would seem that a single year of rotating internship, no matter how carefully planned or supervised, is inadequate graduate preparation. Many of the medical schools have incorporated student externships, family care programs, general practice clinics, and other approaches in an effort to give the undergraduate some concept of the challenge and scope of this field of activity. A few institutions have developed graduate experiences of two years or longer designed to offer better preparation for this area of practice. Currently medical educators face the challenge of careful evaluation of the needs in graduate education for those who choose this field and development of programs that will reflect the same thought and consideration that has been given to graduate medical education in the narrower specialty fields. Trends in specialization will not eradicate, in the foreseeable future, needs for well-qualified and highly competent personnel in the field of general or family practice. Is it not time, therefore, that every effort should be made to assure the same high standards of preparation for "specialists" in this important field as have been given to the preparation of personnel in the narrower specialties? Such developments will involve analysis of the current needs and definition of the scope of general or family practice today and its potential future in order to design graduate educational programs of maximum value.

CURRICULUM—A RACECOURSE OR A WELL-PLANNED PROGRAM?

Literally translated from the Latin, the word curriculum means "a running" or "a racecourse." In its usually accepted sense, it is interpreted as meaning a course of study or the whole body of courses offered in an educational institution or in one of its departments. Knowledge of science and human behavior applicable to the field of medicine is currently accumulating at such a rapid rate that those responsible for the development of the course of study in a medical school are constantly confronted by the challenge of preventing the curriculum from becoming a racecourse rather than a well-balanced program.

In the foreword to the Proceedings of the First World Conference on Medical Education, Sir Lionel Whitby [1] indicates that "the curriculum, important as it is, is no more—and no less—than the structure of medical education; and this structure is given significance by the spirit that informs it and the functions that are fulfilled within it." Deitrick and Berson [2] in the introduction to the report of the survey "Medical Schools in the United States at Mid-Century" call attention to the fact that "in the educational program of a medical school the quality of the faculty and its attitude towards and interest in education are more important than the exact organization of the curriculum." They furthermore state that "a curriculum can be sound only if it is designed for the student and based on sound educational principles. The curriculum must be designed by the faculty as a whole. Each department must see clearly the complete sphere of the program before considering its own segment, and with the student the paramount interest in mind."

Traditional patterns developed in curriculum planning are difficult to readjust unless those who are charged with the responsibility of the curriculum's organization are fully aware of the areas requiring modification in light of the constantly changing scene. No one person in a medical school setting can effectively accomplish it. No small group within a medical school can keep a curriculum dynamic and reasonably balanced unless it effectively represents all facets of the total curriculum content and has a clear-cut concept of the objectives of the total program. It is difficult to readjust traditional allocations of time that require major modification in courses unless curriculum planners have sound knowledge and perspective. Too frequently there is a tendency to add to the curriculum without the preliminary or associated subtraction that is imperative if the total program is to be meaningful.

Departments sometimes indicate that they cannot reduce time and maintain an effective program. It is doubtful that there is any area in a medical curriculum that cannot be modified to fit into a reorganized program if there is complete understanding and full appreciation of the need for such readjustment. Information of details, sometimes forgotten as soon as courses are passed, can be effectively replaced by programs designed to give sound concepts that, in the long run, may represent a more permanent acquisition of knowledge. Curriculum changes made with resentment, lack of full understanding, or unwillingness to modify course content in keeping with modified time allocations may be unrewarding. Those made with widespread knowledge and acceptance of the objective in the total program and entered into with understanding cooperation can achieve the desired ends. Thus, the effectiveness of the curriculum in a medical school does center on the quality of the faculty and its attitude toward and interest in medical education. Unless each department is aware of the total program and its role in it and fully conscious of the changes that necessitate modifications of time allocations and course content, curriculum planning can indeed result in a racecourse for the student rather than the well-balanced educational opportunity it should be.

MEDICOLEGAL SYMPOSIUMS IN OCTOBER

Lawyers and physicians will be taking a major step toward better understanding in the medicolegal field when they meet together at three regional symposiums in October (see this issue, page 611). The need for closer cooperation becomes more apparent with each additional change in our already complex laws and with the many advances in medical science. The Law Department and the Committee on Medicolegal Problems of the American Medical Association are sponsoring this series of meetings where the two professions may discuss important medicolegal subjects and exchange information.

This is an encouraging move at a time when the physician is becoming increasingly aware of the duties, responsibilities, and privileges involved in his somewhat unusual relationship with the law. Busy with practice and research, the physician may not know of or be able to meet the demand on his time and energy that may be necessary in his medicolegal role. A good working relation between the legal and medical professions is needed not only by the two professions but by the public. Working together and with the courts, the two professions should be able to iron out many of the difficulties that harass the lawyers and physicians, particularly in the fields of criminal investigation, expert testimony, and professional liability.

The success of interprofessional discussions in numerous localities is an indication of the gains that can be anticipated through larger meetings drawing participants from wider areas. The opportunities for good in this field are large. The cooperation of the profession in planning the symposiums and the enthusiasm displayed through advance registration thus far give promise of attaining these potentialities.

---

ORGANIZATION SECTION

FEDERAL MEDICAL LEGISLATION

First Session, 84th Congress

Medical Facilities Survey and Construction Act of 1955

Congressman Davidson (D., N. Y.) proposes, in H. R. 7838, "to amend the hospital survey and construction provisions of the Public Health Service Act to provide assistance to the States for surveying the need for psychiatric hospitals, psychiatric treatment and rehabilitation facilities, and facilities for the diagnosis, treatment, and care of narcotic addicts, and to provide assistance in the construction of such facilities through grants to public and nonprofit agencies, and for other purposes." This amendment would authorize 75 million dollars in matching grants over a three year period for construction and $750,000 to assist the states in making surveys of their existing psychiatric facilities for drug addicts. Assistance could not exceed 50% of costs, but each state's allotment would not be less than $25,000. This bill was referred to the Committee on Interstate and Foreign Commerce.

Federal Scholarships for Scientific Subjects

Congressman Powell (D., N. Y.) has introduced, in H. R. 6176, a similar bill to his H. R. 2179, previously reported. This would authorize the Commissioner of Education to award scholarships for college or graduate study in engineering, physics, chemistry, or similar scientific subjects, which could include medicine. A commission of 12 would advise the Commissioner of Education on administration of this program. Both measures were referred to the Committee on Education and Labor.

MEDICOLEGAL SYMPOSIUMS PLANNED

More than 300 physicians and attorneys are expected to attend each of three medicolegal symposiums planned for Oct. 9, 16, and 30 in Chicago, Omaha, and New York City under the sponsorship of the A. M. A. Law Department and the Committee on Medicolegal Problems. Some of the subjects to be discussed include the physician's role in investigating violent deaths, the increasing number of unjustified professional liability suits, and the responsibility of physicians and lawyers in assuring unbiased medical testimony in personal injury cases.

The meetings are intended to improve the understanding by each profession of the problems of the other and to make the result of medical-legal contact more successful for both professions and the public. C. Joseph Stetler, Director of the Law Department, is directing the series of meetings. Among physicians and attorneys who will participate will be Dr. Elmer Hess, A. M. A. President; Dr. George F. Lull, Secretary-General Manager; James R. Reuling, Trustee; Dr. Louis J. Regan, Los Angeles, physician and attorney; Dr. Alan R. Moritz, Cleveland, Chairman of the Committee on Medicolegal Problems, and Irving Goldstein, Chicago, legal authority.

A feature of the symposiums will be a demonstration illustrating a medical expert witness under direct and cross examination. The witness will be Dr. Ralph E. DeForest, Secretary of the Council on Physical Medicine and Rehabilitation, who will be examined by R. G. Van Buskirk and Edwin J. Holman of the Law Department staff. Conference chairman will be: Chicago—Dr. Harlan English, Danville, Ill.; Omaha—Dr. Joseph D. McCarthy, Omaha; New York—Dr. David B. Allman, Atlantic City, N. J. Other participating physicians will be Eric Oldberg, L. Willard Shabat, and Roland P. Mackay, Chicago; Richard Ford, Boston; John Gilligan, Nebraska City, Neb.; and Samuel Brock, New York City.

ANNUAL CONFERENCE ON PHYSICIANS AND SCHOOLS

The fifth annual Conference on Physicians and Schools, sponsored by the A. M. A. Bureau of Health Education, will be held Oct. 12-14 at the Hotel Moraine, Highland Park, Ill. These conferences are designed to explore policies for joint action by those in public health, education, and medicine that will lead to the development of effective health services for school children and to explore the influence of today's pattern of living on the health and behavior of children. Much of the program is given to discussion groups. Among the speakers on the program will be Surgeon General Leonard Scheele, U. S. Public Health Service, and Samuel Brownell, commissioner, Office of Education, U. S. Department of Health, Education, and Welfare. Dr. James R. McVay, Kansas City, Mo., member of the A. M. A. Board of Trustees, will preside at the dinner the evening of the first day, and A. M. A. President Elmer Hess will be the principal speaker.

QUARTERLY CUMULATIVE INDEX MEDICUS

Volume 53 of the Quarterly Cumulative Index Medicus, covering literature for the first half of 1953, has been mailed to subscribers and is now available for purchase from the Order Department of the American Medical Association. It is expected that the next volume will be in the final stages of production by the end of the year. Beginning Jan. 1, 1956, the subscription rate for the Index will be increased to $25 per year and the price for a single volume to $15. However, any orders for volumes due in 1953, 1954, and 1955 placed in advance of this date will be honored at the old rates.

The Federal Medical Legislation summary is prepared by the Washington Office of the American Medical Association.

MEDICAL NEWS

CALIFORNIA

Workmen's Compensation Lectures.—Lectures on California workmen's compensation will be given at the University of California Extension Center, 813 S. Hill St., Los Angeles, on Mondays, 7-9 p. m., for 15 weeks beginning Oct. 10. Douglass A. Campbell, referee with the California Industrial Accident Commission, will serve as instructor.

Hospital News.—Samuel Merritt Hospital, Oakland, has changed its organization from a trusteeship to a nonprofit corporation. The Merritt Hospital, a 40-bed institution in 1909, has grown to a 7 million dollar, 225-bed medical center under a three man trusteeship, established to carry out the wishes of Dr. Samuel Merritt, a pioneer doctor and former mayor of Oakland. The new seven-man board of directors includes Drs. George G. Reinle, president, and William Earl Mitchell, vice-president (trustees), and Drs. James A. Barr and Philip N. Baxter.

Annual Practitioners Meeting.—The seventh annual scientific assembly of the California Academy of General Practice will convene at the Palace Hotel, San Francisco, Oct. 9-12. Presentations by out-of-state speakers will include:

Teen-Age Gynecology, Goodrich C. Schauffler, Portland, Ore.
Background of Coronary Artery Disease, William H. Gordon, Lubbock, Texas.
Obesity and Thinness; Which Goiters are Best Treated with Radioactive Iodine and Which with Surgery? Edward H. Rynearson, Rochester, Minn.
Migraine and Vascular Headaches, Perry S. MacNeal, Philadelphia.
Present Day Aspects of Cancer of the Intestinal Tract, Edward S. Judd Jr., Rochester, Minn.
The Acute Surgical Abdomen in Infancy and Early Childhood, Charles W. McLaughlin Jr., Omaha.
Cancer of the Uterus: Diagnosis and Treatment, Joe V. Meigs, Boston.

A live clinic on pulmonary disease problems has been scheduled for Tuesday, 1:30 p. m. The dinner dance (informal) will be held at 7:30 p. m. Tuesday.

CONNECTICUT

Yale Society Meeting.—Dr. Charles Gardner Child III, professor of surgery, Tufts College Medical School, Boston, will present before the Yale Medical Society at 8:15 p. m. Oct. 10 in the Fitkin Amphitheater at the Yale-New Haven Medical Center "The Surgical Physiology of Portal Hypertension." All physicians are invited.

DISTRICT OF COLUMBIA

Annual Scientific Assembly.—The Medical Society of the District of Columbia will hold its 25th annual scientific assembly at the Hotel Statler, Washington, D. C., Oct. 10-12. The address of welcome by Dr. W. Ross Morris, president, Monday, 9:15 a. m., will be followed by "The Scientific Basis for Surgical Treatment of Coronary Disease" by Dr. Claude S. Beck, Cleveland; "The Clinical Aspects of Surgery for Coronary Disease" by Dr. Bernard L. Brofman, Cleveland; "Evaluation of the Antipoliomyelitis Program" by Drs. Thomas Francis Jr., Ann Arbor, Mich., and Robert F. Korns, Albany, N. Y.; and "The Veterans Administration Hospital Program" by Dr. William B. Walsh, Washington, D. C. The afternoon session will open with a symposium on diagnostic and therapeutic uses of radioisotopes, with Dr. Oscar B. Hunter Jr., Washington, D. C., as moderator. The symposium will be followed by "Therapy of Far Advanced Carcinoma of the Breast" by Dr. James R. Maxfield Jr., Dallas, Texas, and "Chemotherapy in Malignant Disease" by Dr. C. Lockard Conley, Baltimore. A symposium on the tissue committee from the viewpoint of the surgeon is scheduled for Wednesday at 10:45 a. m., and a clinicopathological conference will be held at 3:15 p. m. Presentations by out-of-state speakers on Tuesday and Wednesday will include:

Obstetrical and Gynecological Applications of the Effect on the Pelvis by Man's Assumption of the Erect Posture, Joshua W. Davies, New York.
Complications of Chlorpromazine Therapy, Jacob Kirshner, New York.
Appraisal of Total Gastrectomy, Karl C. Jonas, Philadelphia.
Newer Aspects of Sympathectomy in Arterial Occlusive Disease, Gerald H. Pratt, New York.
Long-Term Anticoagulants in Coronary Atherosclerosis, E. Sterling Nichol, Miami, Fla.
Problem of the Solitary Pulmonary Nodule, C. Allen Good, Rochester, Minn.
Esophagitis—A Common Condition *Frequently Overlooked*, Herbert W. Schmidt, Rochester, Minn.
Newer Aspects of Therapy in Infectious Hepatitis, Thomas C. Chalmers, Boston.
Recent Advances in Studies in Infertility, Fred A. Simmons, Boston.
Coagulation Defects in the Postpartum Period, Arthur Sawitsky, Jamaica, N. Y.
Early Stages in Development of Carcinoma of the Cervix, Leland D. Stoddard, Augusta, Ga.
Differential Diagnosis of Hemorrhagic Disease, Kenneth M. Brinkhous, Chapel Hill, N. C.
Secondary Hemolytic Disease in Malignancy and Uremia, Ernest E. Muirhead, Dallas, Texas.
Some New Concepts of Thyroid Dysfunction, Henry H. Turner, Oklahoma City.

ILLINOIS

Psychiatric Lecture.—Dr. Francis J. Gerty, professor and head of the department of psychiatry at the University of Illinois College of Medicine, will present "The Use and Abuse of Sedatives and Stimulants" Nov. 2, 8 p. m., at the North Shore Health Resort, 225 Sheridan Rd., Winnetka.

Chicago

Personal.—Dr. Adolph Rostenberg, professor of dermatology, University of Illinois College of Medicine, will serve as moderator for a panel on cutaneous allergy during a course in occupational skin problems for physicians, which will be presented by the department of preventive medicine and industrial health, University of Cincinnati, Oct. 10-14.

Hektoen Lecture.—The Hektoen Institute for Medical Research of the Cook County Hospital announces that the second Dr. Ludvig Hektoen Memorial Lecture will be delivered by Prof. Herwig Hamperl, director of the Pathological Institute of the University of Bonn, Germany, on nutrition and disease at 8 p. m. Oct. 12 in the amphitheater of the department of pathology of Cook County Hospital, 1825 W. Polk St., Chicago 12.

Lectures on Cancer.—Northwestern University Medical School will present its annual series of cancer lectures for members of the medical profession on Wednesdays, 5-6 p. m., Oct. 12-Nov. 23, in the auditorium of the Veterans Administration Research Hospital, 333 E. Huron St. Dr. William B. Wartman, chairman, department of pathology, Northwestern University Medical School, is coordinator of the lectures. The programs for October are as follows:

Oct. 12, Pathology of Cancer of the Lung Correlated with Diagnosis, Treatment and Prognosis, Lauren V. Ackerman, St. Louis.
Oct. 19, Comparison of Adult, Embryonic, and Cancer Tissues, Harry S. N. Greene, New Haven, Conn.
Oct. 26, Studies on the Mechanism of Hydrocarbon Carcinogenesis, Charles Heidelberger, Ph.D., Madison, Wis.

Fire Prevention Week.—During Fire Prevention Week, Oct. 9-15, 16 hospitals that have received emergency training from the Fire Prevention Bureau will participate in a special program, in cooperation with the Chicago Hospital Council, Greater Chicago Safety Council, the Program Committee, and the Fire Prevention Bureau. Demonstrations will include fire escape drills and fire emergency demonstrations. A demonstration on a fireboat, scheduled for 11 a. m. Thursday, will be followed by an award luncheon and theater party.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

Robert A. Black Lecture.—Dr. Lewis Thomas, professor of pathology, New York University School of Medicine, will deliver the third Robert A. Black Lecture, "The Origin and Nature of Fibrinoid," at La Rabida Jackson Park Sanitarium Oct. 14, 12 noon, as part of the staff scientific meeting, which begins at 10 a. m. All physicians are invited.

Orthopaedic Society Meeting.—The Chicago Orthopaedic Society will hold a meeting at the Palmer House Oct. 14 in private dining room 17. The following program will be presented at 8 p. m.:

Studies on the Use of Cultured Calf Bone in Human Bone Grafts—A Complete Presentation of This Subject, Using Motion Pictures and Photomicrographs, E. J. Tucker, Houston, Texas.

The Antigenicity of Homogenous and Homologous Bone Grafts—Results of Histological Study of Bone Grafts and Host Response in Immunologically Prepared Animals and Control Animals, William F. Enneking, Chicago.

Immunology of Bone Transplants—Studies of a Host Rejection to Bone Grafts and Experimental Attempts to Control This Inflammatory Response, Michael Bonfiglio, Iowa City.

Drs. C. Howard Hatcher, Chicago, and Charles F. Gregory, Indianapolis, will discuss the papers. Cocktails, 6 p. m., and dinner will precede the program. All physicians are cordially invited.

Joint Meeting and Heart Clinic.—The Englewood, Jackson Park, South Chicago, South Side, and Stock Yards branches of the Chicago Medical Society and the Chicago Heart Association will hold a joint meeting Oct. 12, 2-6 p. m., at the University of Chicago Clinics, pathology 117 (amphitheater), 950 E. 59th St. (Phone: MIdway 3-0800). A cardiac clinic conducted by faculty members of the University of Chicago School of Medicine will include: "A Case of Rheumatic Heart Disease" (discussion opened by Dr. Albert Dorfman); "A Case of Refractory Congestive Failure" (discussion opened by Dr. Robert G. Page); "A Case of Combined Lung Failure and Heart Failure" (discussion opened by Dr. Robert H. Ebert); and "A Case of Mitral Valvulotomy" (discussion opened by Dr. Richard J. Jones and Dr. William E. Adams). Dr. Wright R. Adams and Dr. George V. LeRoy will preside. All physicians are welcome.

LOUISIANA

Dedication of the Hutchinson Building.—Dedication of the new 10-story addition to the Hutchinson Memorial Medical Building, which houses the school of medicine at Tulane University, New Orleans, will be held Oct. 13-16. The Thursday dedication exercises will be presided over by Dr. Maxwell E. Lapham, dean of the school of medicine. The principal address will be delivered by Dr. Andrew J. Warren, former director of the division of medicine and public health, Rockefeller Foundation, New York. Other speakers include Dr. Cassius J. Van Slyke, associate director, National Institutes of Health, Bethesda, Md.; Joseph M. Jones, LL.B., president of the Tulane board of administrators; Rufus C. Harris, LL.D., Tulane president; Dr. William W. Frye, dean of the Louisiana State University School of Medicine; and the Rev. Sherwood Strobel Clayton, rector of Grace Episcopal Church. At 2 p. m. a panel on medical education will be held under the chairmanship of Dr. Clifford G. Grulee, New Orleans. Participants will include Dr. Lester J. Evans, New York; Dr. Granville A. Bennett, Chicago; and Dr. John W. Patterson, Cleveland. On Friday scientific sessions will be held on medicine, pathology, psychiatry and neurology, microbiology, and pharmacology. Sunday sessions will feature programs and demonstrations to be staged by faculty members of all departments of the school. Open house and a reception will be held from 3 to 5 p. m., including a tour of the building and inspection of exhibits and demonstrations. The public is cordially invited.

MINNESOTA

Society News.—A joint meeting of range and county medical societies, Oct. 13 at the Androy Hotel in Hibbing, will have as guest speaker Dr. George A. Hellmuth, chief of cardiology, Marquette University School of Medicine, Milwaukee, whose topic will be "Diagnosis and Treatment of Serious Cardiac Arrhythmias."

NEW YORK

County Society Meeting.—The monthly meeting of the Broome County Medical Society will be held Oct. 11, 8:45 p. m., at Binghamton City Hospital, Binghamton. Mr. Richard M. Stalvey, administrative assistant, Bureau of Investigation, American Medical Association, Chicago, will deliver a paper entitled "Beware of Gadgets That Cure."

Society News.—The Medical Society of the County of Erie will be the guests of the Pfizer Laboratories of Brooklyn at a dinner party and lecture in the ballroom of the Hotel Statler in Buffalo Oct. 10. Sir Harold Scott of London, who was head of Scotland Yard for eight years, will discuss "Scotland Yard at Work." The dinner meeting and lecture will be preceded by a cocktail party at 6:30 p. m.

New York City

Personal.—Dr. Philip H. Sechzer was recently appointed assistant professor, department of anesthesiology, New York University Postgraduate Medical School.——Dr. Harry M. Zimmerman, chief, laboratory division, Montefiore Hospital, recently went to Israel to discuss with officials of the two organizations building plans for the new medical school to be incorporated in the $12,500,000 Hadassah-Hebrew University Medical Center. En route, Dr. Zimmerman read a paper on brain tumors before the International Congress of Neuropathology in London, England.——Dr. Leonard H. Schuyler has been appointed an assistant medical director of the American Heart Association, where he will aid in administration of the research support and professional education programs.——Dr. Arthur Alexander Knapp was recently invited to be a guest at the global strategy discussions at the U. S. Naval War College at Newport, R. I.

Annual Academy Fortnight.—The 28th annual Graduate Fortnight of the New York Academy of Medicine will be concerned with "Problems of Aging." The meetings, Oct. 10-21, will be held at the academy, 2 E. 103rd St. The following panel meetings have been scheduled: Aging and Atherosclerosis; Everyday Problems in the Care of the Aged; Management of Cardiovascular Renal Problems in the Aged; Management of Prostatic Obstruction; Public Health Aspects of Aging; and Problems of Infectious Diseases and Their Therapy in the Aged. The afternoons will be devoted to hospital clinics. The opening address will be delivered Oct. 10, 8:30 p. m., by Dr. Edward J. Donovan, president of the academy, after which the Ludwig Kast Lecture, "What Is Aging?" will be delivered by Albert I. Lansing, Ph.D., professor of anatomy, Emory University School of Medicine, Emory University, Ga. The evening session Oct. 11 will open with presentation of "Arthritis in the Elderly Patient" by Dr. Joseph J. Bunim, clinical director, National Institute of Arthritis and Metabolic Diseases, Bethesda, Md. The Wesley M. Carpenter Lecture, "Some Physiological Aspects of Aging," will be delivered Oct. 12, 8:30 p. m., by Nathan W. Shock, Ph.D., chief section on gerontology, National Heart Institute, Bethesda, Md., and of the Baltimore City Hospitals. The evening session Oct. 13 will be devoted to a panel meeting on cerebrovascular disease with aging and the evening session Oct. 14 to a panel meeting on problems of retirement. During the second week the Harlow Brooks Lecture, "The Nature of the Response to Stress with Aging," by Dr. James L. Whittenberger, professor of physiology, Harvard School of Public Health, Boston, will open the Monday evening session. On Thursday evening there will be a panel meeting, "Gonadel Function and Involution in Man—and Related Practical Management" and on Friday evening a panel meeting, "Disorders of the Special Sense Organs Associated with Aging: Their Recognition and Treatment."

UTAH

Health Commissioner Sought.—Dr. James Z. Davis, Salt Lake City, who is serving as chairman of the state board of health, has been appointed to coordinate operations of the state health department in the absence of a health commissioner. A special committee, headed by Dr. Charles Ruggeri Jr., Salt Lake City, is continuing its search for a commissioner to replace Dr. George

A. Spendlove, who resigned to become assistant director of public welfare for the state of Washington. Assisting Dr. Davis is Dr. Joseph P. Kesler, assistant public health director and director of the state children's health center at Fort Douglas, who has been appointed active director of the department.

WEST VIRGINIA

Society News.—The annual meeting of the West Virginia Heart Association will be held in the Hotel McLure in Wheeling Oct. 13. A wet clinic session is scheduled at the Wheeling Hospital nurse's home at 10 a. m. The scientific session at the McLure at 2 p. m. will be followed by the annual business meeting. A social hour at 6 p. m. will precede the annual dinner.

GENERAL

Nominations for Lederle Awards.—The closing date for nominations for Lederle Medical Faculty awards to be made during the academic year 1956-1957 is Oct. 31. Nominations will be received from deans of medical schools or, with their approval, from the heads of preclinical departments of medical schools in the United States and Canada and should be addressed to Office of the Secretary, Committee for Lederle Medical Faculty Awards, Pearl River, N. Y., where information may be obtained. The awards will be announced on or before Jan. 15, 1956.

Meeting on Cerebral Palsy.—The American Academy for Cerebral Palsy will hold its annual meeting at the Claridge Hotel in Memphis, Tenn., Oct. 10-12 under the presidency of Dr. Lenox D. Baker, Durham, N. C. The meetings are open to members of the medical and allied professions. The program will include instructional courses in the various phases of cerebral palsy as well as a formal program. Those wishing to attend may obtain an invitation on request to Dr. Robert A. Knight, Secretary-Treasurer, 869 Madison Ave., Memphis 3, Tenn.

Oak Ridge Traveling Lecture Program.—During the academic year 109 scientists from Oak Ridge, Tenn., will make available their services as lecturers to colleges and universities, particularly to those in the Southern region, as part of the Atomic Energy Commission's program of disseminating information to institutions of higher education. The Oak Ridge scientists will travel on request to university campuses under the Oak Ridge Traveling Lecture Program, a joint activity of the Oak Ridge National Laboratory and the Oak Ridge Institute of Nuclear Studies. The speakers, their topics, touching virtually every field of scientific endeavor, and instructions on request for lecturers are listed in the brochure, which may be obtained by writing: Chairman, University Relations Division, Oak Ridge Institute of Nuclear Studies, P. O. Box 117, Oak Ridge, Tenn.

Fellowships for Women.—The American Association of University Women will offer 28 fellowships to American women for advanced study or research during the academic year 1956-57. In general, the $2,000 fellowships (18 unrestricted; 2 for study outside the United States; 1 for research in chemistry, physics, or biology) are awarded to young women who have completed residence work for the Ph.D. degree or who have already received the degree; the $2,500-$3,500 awards, all unrestricted, are given to more mature scholars. Applications must reach the association's office in Washington, D. C., by Dec. 15, 1955. For information, address the Secretary, Committee on Fellowship Awards, American Association of University Women, 1634 Eye St., N. W., Washington 6, D. C. American women are eligible for a number of international fellowships contributed by the association, which are awarded by the International Federation of University Women. The successful candidate must study outside her own country, but there is no restriction as to subject.

Rhinologic Society Meeting.—The annual meeting of the American Rhinologic Society will be held at the Palmer House, Chicago, on Oct. 8. Dr. Maurice H. Cottle, Chicago, president, will deliver the address of welcome after the reception and breakfast at 8 a. m. During a symposium on septum surgery, Dr. Walter E. Loch, Baltimore, will present "Submucous Resection Operation: Its Status After 50 Years," and "Submucous Reconstruction Operations" will be presented by Dr. Robert M. Hansen, Portland, Ore. ("Metzenbaum Modifications"); Dr. Walter J. Aagesen, Anderson, Ind. ("Eastern Group Approach"); and Dr. Kenneth H. Hinderer, Pittsburgh ("Total and Subtotal Replacements"). Dr. Ralph H. Riggs, Shreveport, La., will serve as moderator for a panel discussion on the symposium topic, with the symposium participants as panelists. Eight presentations will be delivered by members (time permitting), or be read by title only. At 2:15 p. m., after the luncheon, guest presentations will be delivered by Dr. Robert Gronner, Northwestern University, Chicago ("The Rhinologist's Patient"), and Thomas P. Dougherty, Ph.D., University of Utah, Salt Lake City ("Connective Tissue, Inflammation, and Steroids"). Cocktails and a reception in honor of the Drs. Gronner and Dougherty will be held at the conclusion of the program.

Pathologists Meeting in Chicago.—The ninth annual session of the College of American Pathologists will convene at the Drake Hotel, Chicago, Oct. 9, 10, 11, and 15, under the presidency of Dr. David A. Wood, San Francisco. The sessions will open Monday with a panel discussion, "Medical Care Plans and the Pathologist," followed by panel discussion on "The Joint Commission on Accreditation of Hospitals and the Pathologist." Panel discussions in the afternoon session will be "Medical Photography" and "University Departments and the Private Practice of Pathology." A fellowship hour is scheduled for 5:30 p. m. Tuesday morning will be devoted to a joint symposium, "The Pathologist as Supervisor of the Clinical Chemistry Division of the Hospital Laboratory," presented by the College of American Pathologists and the American Society of Clinical Pathologists, with Dr. Frank W. Konzelmann, Washington, D. C., as moderator. A joint fellowship hour, 6-7:30 p. m., will precede the joint banquet at which the distinguished speaker will be Charles F. Kettering, Sc.D., Detroit. A round-table luncheon will be jointly sponsored by the society and the college Wednesday at 12:30 p. m. Under the same joint sponsorship, workshops (Use of Radioisotopes in the Clinical Laboratory, Ophthalmic Pathology, Medical Writing, and Microbiology) and refresher courses (Histochemistry, Dermal Pathology, Bone Marrow Interpretation, and Cytology) will be presented on Saturday.

Academy of Ophthalmology and Otolaryngology.—The American Academy of Ophthalmology and Otolaryngology will hold its 60th annual meeting at the Palmer House, Chicago, Oct. 9-14. All members and guests are invited to a reception honoring Dr. and Mrs. Alan C. Woods, Baltimore, and Dr. and Mrs. Philip E. Meltzer, Boston, Sunday, 4:30 p. m. The honor guest, Sir Norman Gregg, Sydney, Australia, will give an address. The following symposium, "The Uses and Abuses of the Corticosteroids in Ophthalmology and Otolaryngology," will be presented:

General Considerations, Rachmiel Levine, Chicago.
Ophthalmologic Aspects, John M. McLean, New York.
Otolaryngologic Aspects, Aubrey G. Rawlins, San Francisco.

Dr. Frederick C. Cordes, San Francisco, will deliver the 12th Jackson Memorial Lecture, "Failure in Congenital Cataract Surgery: A Study of Fifty-Six Enucleated Eyes," before the section on ophthalmology Tuesday at 9:10 a. m. The 11th Wherry Memorial Lecture, "Local Reactions to Infections and Allergies," will be presented by Dr. Edmund P. Fowler Jr., New York, at the meeting of the section on otolaryngology Wednesday at 2:55 p. m. At the closing meeting of the section on ophthalmology Friday morning Sir Norman Gregg will present "The Relationship of Infections in the Early Months of Pregnancy to Congenital Anomalies." The section on otolaryngology has scheduled symposiums on Menière's disease and on errors in the early diagnosis and treatment of cancer in the upper respiratory tract. The section on ophthalmology will present a symposium on diseases of the optic nerve. At its closing session it will hear an invitational address "The Aging of the Retina" by Prof. A. Pillat, Vienna, Austria, and will view "The Effect of Oxygen on Retinal Vessels" and "Goniodialisis," motion pictures, presented respectively, by Dr. Norman Ashton, London, England, and Dr. Olga Ferrer, Havana, Cuba. Dr. Gunnar Heuser, Montreal, Canada, has been invited to discuss "Stress in Disease" before the opening meeting of the section on otolaryngology Monday afternoon.

Conference on Tuberculosis.—"Tuberculosis, the Job Is Not Done" will be the theme of the 42nd annual meeting of the Mississippi Valley Conference on Tuberculosis at the Hotel Savery, Des Moines, Iowa, Oct. 13-15, under the presidency of Dr. Harold M. Coon, Madison, Wis. The Mississippi Valley Trudeau Society (Dr. Ejvind P. K. Fenger, Oak Terrace, Minn., president), which will have a joint meeting with professional tuberculosis control workers on Thursday, will hold its scientific session Friday when the following program will be presented:

Report on the Present Status of Antimicrobial U.S.P.H.S. Cooperative Study, Harold I. Humphrey, Columbus, Ohio.
Respiratory Diseases Transmitted from Animals to Man, James H. Steele, D.V.M., chief veterinarian, U. S. Public Health Service, Atlanta, Ga.
Fungus Diseases of the Lungs, Norman F. Conant, Ph.D., Durham, N. C.
Bilateral Resection for Pulmonary Tuberculosis, Joseph W. Gale, Madison, Wis.
Pulmonary and Associated Problems in the Aging Population, Martin J. Fitzpatrick, Kansas City, Kan.
Acute Respiratory Diseases—Studies of Recently Identified Respiratory Viruses (Clinical and Epidemiological), William S. Jordan, Cleveland.
Chronic Suppurative Pulmonary Diseases, Medical: Oscar Bigman and Nicholas H. DeJanney, Detroit; Surgical: Hiram T. Langston, Chicago.
Pulmonary Physiology in Clinical Practice, Steven M. Horvath, Ph.D., Iowa City.
Inhalation Therapy in Pulmonary Diseases, Arthur M. Olsen, Rochester, Minn.

Dr. Walter L. Bierring, Des Moines, will preside at a joint evening session about "World Health Problems and Tuberculosis," for which the speakers will be Dr. John D. Steele, immediate past-president, American Trudeau Society, and chief of surgery, Veterans Administration Hospital, San Fernando, Calif., and Dr. Henry Van Zile Hyde, chief of division, international health, U. S. Department of Health, Education and Welfare, Washington, D. C. The Iowa Academy of General Practice will grant five hours of informal credit to physicians attending the day-long medical meeting on Friday.

Clinical Fellowships in Radiation Therapy.—The American Cancer Society Clinical Fellowships in Radiation Therapy are offered in 1956-1957 to qualified graduates in medicine who have already received thorough basic training in the principles and practice of radiation therapy and who desire to spend additional periods of training in that specialty at certain clinics in the United Kingdom, the Scandinavian countries, and France. Fellowships are available to citizens of the United States under 40 years of age who are graduates of recognized medical schools in the United States and who have previously received training in therapeutic radiology acceptable to the American Board of Radiology as credit toward certification. In the selection of applicants, priority will be given to physicians who (1) are already certified by the American Board of Radiology, (2) who have completed the required training in preparation for board examinations but who have not yet taken the examinations, and (3) those who, while intending to complete board requirements and take the examinations, are still in the training period. The annual stipend for fellows in radiation therapy is $4,500, including travel. American Cancer Society fellows in radiation therapy may choose to spend the entire fellowship year in one institution or to divide the time between two or more; in the latter event, however, at least eight months must be served in a single institution in order that a reasonable measure of practical experience rather than observation only may be assured. Candidates will file three letters of recommendation with their application. Further information and application forms may be procured from the American Cancer Society, Inc., Professional Education Section, 521 W. 57th St., New York 19.

Medical Research Fellowships.—The division of medical sciences of the National Academy of Sciences-National Research Council is accepting applications for postdoctoral research fellowships for 1956-1957. These awards are designed to offer research experience for promising individuals who look forward to investigative careers rather than to provide practical experience in the clinical field. Ordinarily fellowships are not granted to persons over 35. The following programs are announced:

Fellowships in Cancer Research: Awarded by the American Cancer Society on recommendation of the committee on growth of the division of medical sciences and available to citizens of the United States for study in all branches of the biological, chemical, and physical sciences and of clinical investigation applicable to the study of growth, typical or malignant.
British American Exchange Fellowships in Cancer Research: Awarded by the American Cancer Society on recommendation by the committee on growth to citizens of the United States for advanced study in Great Britain in specialized fields pertaining to the problem of growth; similar fellowships are awarded by the British Empire Cancer Campaign to young British scientists for research in the United States.
Fellowships in the Medical Sciences: Supported by the Rockefeller Foundation and administered by the medical fellowship board of the division, these awards are open to citizens of the United States and Canada who expect to devote themselves to research in the basic medical sciences.
Fellowships in Tuberculosis: Administered by the medical fellowship board under a grant from the National Tuberculosis Association and designed to promote the development of investigators in fields related to tuberculosis, they are open to citizens of the United States who are graduates of American schools.
Fellowships in Radiological Research: Administered for the James Picker Foundation by the division's committee on radiology, appointments, not limited to citizens of the United States, are open to candidates seeking to gain research skills leading to investigative careers in the field of radiology.

Applications for 1956-1957 under any of these programs must be postmarked on or before Dec. 1, 1955. Fellowships are awarded in the early spring. Application blanks may be obtained from the Fellowship Office, National Academy of Sciences-National Research Council, 2101 Constitution Ave., N. W., Washington 25, D. C.

LATIN AMERICA

Pan-American Convention.—The fourth General Assembly and the fifth Pan-American Medical Social Convention will be held in Bogota, Colombia, under the auspices of the Colombian government and the Medical Federation of Colombia Oct. 15-22. The official topic for the congress is "Mental Hygiene." Roundtable discussions on cardiovascular surgery, nutrition, and infection have also been scheduled.

FOREIGN

Belgian Congo Needs a Physician.—According to Melville O. Williams Jr., Ed.D., secretary for missionary personnel of the Board of Missions of the Methodist Church, a physician-surgeon is needed to serve mission hospitals in the central Belgian Congo. Applicants should be experienced in general medicine and surgery and be, preferably, under 35 years of age. A married man with children will be acceptable, as there are both elementary and high school facilities. Persons interested in such a three year missionary term, or those knowing of a possible applicant, are asked to contact Dr. Williams, 150 Fifth Ave., New York 11.

Antitrachoma Drives.—Nearly a million school children in Formosa are being treated in a mass campaign against trachoma under the United Nations Children's Fund. The drive, which began in the fall of 1954 after a pilot project revealed that 50% of the 1,300,000 children in schools were infected with trachoma and 25% were infected with other forms of conjunctivitis, is to be completed in a period of 18 months. A health education program is part of the campaign. Similar mass drives against trachoma are being conducted by UNICEF in Morocco, Tunisia, Yugoslavia, Egypt, and Spain. In Morocco it is hoped that half a million people, including 100,000 children, will be reached by the middle of 1956. In Tunisia 218,000 people were treated for eye disease during 1954. A pilot project is in progress in Egypt, where more than 70% of all the blindness is the result of corneal ulceration complicating acute conjunctivitis in childhood. The pilot project includes education in sanitation and an attempt to control infection-carrying insects, especially Musca sorbens, believed to be an important vector.

CORRECTION

Escherichia Coli.—In Stiles and Weir's Clinical Note in THE JOURNAL, Aug. 20, 1955, page 1432, in the 13th line from the bottom of the first column the words "Endamoeba coli" should have been "Escherichia coli."

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1955 Clinical Meeting, Boston, Nov. 29-Dec. 2.

1956 Annual Meeting, Chicago, June 11-15.

1956 Clinical Meeting, Seattle, Nov. 27-30.

1957 Annual Meeting, New York, June 3-7.

National Conference on Physicians and Schools, Moraine-on-the-Lake Hotel, Highland Park, Ill., Oct. 12-14. Dr. W. W. Bauer, 535 N. Dearborn St., Chicago, Director.

National Medical Public Relations Conference, Hotel Statler, Boston, Nov. 28. Mr. Leo F. Brown, 535 N. Dearborn St., Chicago 10, Director.

American Academy for Cerebral Palsy, Claridge Hotel, Memphis, Tenn., Oct. 10-12. Dr. Robert A. Knight, 869 Madison Ave., Memphis 3, Tenn., Secretary.

American Academy of Dermatology and Syphilology, Palmer House, Chicago, Dec. 3-8. Dr. James R. Webster, 55 East Washington St., Chicago 2, Secretary.

American Academy of Neurological Surgery, The Homestead, Hot Springs, Va., Oct. 27-29. Dr. Eben Alexander Jr., Bowman Gray School of Medicine, Winston-Salem, N. C , Secretary.

American Academy of Ophthalmology and Otolaryngology, Palmer House, Chicago, Oct. 9-14. Dr. W. L. Benedict, 100 First Avenue Bldg., Rochester, Minn., Executive Secretary.

American Association of Blood Banks, Palmer House, Chicago, Nov. 19-21. Miss Marjorie Saunders, 3707 Gaston Ave., Dallas 10, Texas, Secretary.

American Association of Medical Clinics, Curtis Hotel, Minneapolis, Nov. 4-6. Dr. Edwin P. Jordan, Box 58, Charlottesville, Va., Executive Director.

American Association for the Surgery of Trauma, Drake Hotel, Chicago, Oct. 27-29. Dr. James K. Stack, 700 N. Michigan Blvd., Chicago 11, Secretary.

American Clinical and Climatological Association, The Homestead, Hot Springs, Va., Oct. 31-Nov. 2. Dr. M. N. Fulton, 124 Waterman St., Providence 6, R. I., Secretary.

American College of Anesthesiologists, Hotel Statler, Boston, Nov. 4-5. Mr. John H. Hunt, 188 West Randolph St., Chicago 1, Executive Secretary.

American College of Cardiology Interim Meeting, Hotel Claridge, Memphis, Tenn., Nov. 10-12. Dr. Philip Reichert, Empire State Bldg., New York 1, Secretary.

American College of Gastroenterology, Hotel Shoreland, Chicago, Oct. 24-26. Dr. Joseph Shaiken, 33 West 60th St., New York 23, Secretary

American College of Surgeons, Conrad-Hilton Hotel, Chicago, Oct. 31-Nov. 4. Dr. Michael L. Mason, 40 East Erie St., Chicago 11, Secretary.

American Dental Association, San Francisco, Oct. 17-20. Dr. Harold Hillenbrand, 222 East Superior St., Chicago 11, General Secretary.

American Heart Association, Yung Hotel, New Orleans, Oct. 22-26. Mr. Irving Hexter, 44 East 23d St., New York 10, Secretary.

American Medical Women's Association, Board Meeting, Netherlands-Plaza Hotel, Cincinnati, Nov. 11-13. Miss Lillian T. Majally, 1790 Broadway, New York 19, Executive Secretary.

American Public Health Association, Muehlebach Hotel and Municipal Auditorium, Kansas City, Mo., Nov. 14-18. Dr. Reginald M. Atwater, 1790 Broadway, New York 19, Executive Secretary.

American School Health Association, Hotel President, Kansas City, Mo., Nov. 14-18. Dr. A. O. DeWeese, 515 East Main St., Kent, Ohio, Secretary.

American Society of Anesthesiologists, Hotel Statler, Boston, Oct. 29-Nov. 3. Dr. J. Earl Remlinger Jr., Room 1101, 188 W. Randolph St., Chicago 1, Secretary.

American Society of Clinical Pathologists, Drake Hotel, Chicago, Oct. 10-15. Dr. Clyde G. Culbertson, 1040-1232 West Michigan St., Indianapolis, Secretary.

American Society for the Study of Arteriosclerosis, Hotel Sheraton, Chicago, Nov. 6-7. Dr. O. J. Pollak, P.O. Box 228, Dover, Del., Secretary.

American Society of Tropical Medicine and Hygiene, Somerset Hotel, Boston, Nov. 2-5. Dr. John E. Larsh Jr., Dept. of Parasitology, School of Public Health, Chapel Hill, N. C., Secretary.

Association of *American Medical Colleges*, New Ocean House, Swampscott, Mass., Oct. 24-26. Dr. Dean F. Smiley, 185 N. Wabash Ave., Chicago 1, Secretary.

Association of Life Insurance Medical Directors of America, Hotel Statler, New York, Oct. 19-21. Dr. Henry B. Kirkland, P. O. Box 594, Newark, N. J., Secretary.

Association of Military Surgeons of the U. S., Hotel Statler, Washington, D. C., Nov. 7-9. Colonel Robert E. Bitner, 1726 I St. N.W., Washington 6, D. C., Secretary.

Association of State and Territorial Health Officers, Hotel Washington, Washington, D. C., Nov. 6-12. Dr. Franklin D. Yoder, State Board of Health, Cheyenne, Wyo., Secretary.

Central Neuropsychiatric Association, The Broadmoor, Colorado Springs, Colo., Oct. 20-22. Dr. Hamilton Ford, 112 North Boulevard, Galveston, Tex., Secretary.

Central Society for Clinical Research, Drake Hotel, Chicago, Nov. 4-5. Dr. Robert H. Ebert, 950 East 59th St., Chicago 37, Secretary.

College of American Pathologists, Drake Hotel, Chicago, Oct. 10-15. Dr. Arthur H. Dearing, 203 N. Wabash Ave., Chicago 1, Executive Secretary.

Congress of Neurological Surgeons, Hotel Statler, Los Angeles, Oct. 27-29. Dr. Philip D. Gordy, 1007 Delaware Ave., Wilmington, Del, Secretary.

Delaware, Medical Society of, Delaware Academy of Medicine, Wilmington, Oct. 17-18. Dr. Norman L. Cannon, 621 Delaware Ave., Wilmington, Secretary.

District of Columbia, Medical Society of the, Hotel Statler, Washington, D. C., Oct. 10-12. Mr. Theodore Wiprud, 1718 M St., N.W., Washington 6, D. C., Executive Director.

Eastern Section, American Federation for Clinical Research, Hotel Warwick and College of Physician's Building, Philadelphia, Dec. 2-3. Dr. Charles R. Shuman, Temple Univ. Hospital, Broad and Ontario Sts., Philadelphia 40, Chairman.

Gerontological Society, Sheraton-Belvedere Hotel, Baltimore, Oct. 27-29. Dr. Nathan W. Shock, Baltimore City Hospitals, Baltimore 24, Secretary.

Gulf Coast Clinical Society, Pensacola, Fla., Oct. 27-28. Dr. Barkley Beidleman, 1750 N. Palafox St., Pensacola, Fla., Secretary.

Indiana State Medical Association, French Lick Springs Hotel, French Lick, Oct. 16-19. Mr. James A. Waggener, 23 East Ohio St., Indianapolis 4, Executive Secretary.

Inter-Society Cytology Council, Statler Hotel, Cleveland, Nov. 11-12. Dr. Paul F. Fletcher, 634 N. Grand Blvd., St. Louis 3, Secretary.

Interstate Post Graduate Medical Association of North America, Municipal Auditorium, Milwaukee, Nov. 14-17. Mr. Roy T. Ragatz, 207 Gay Bldg., Madison 3, Wis., Executive Director.

Medical Society Executives Conference, Boston, Nov. 27. Mr. H. Martin Baker, 1102 South Hillside, Wichita 17, Kansas, Secretary.

Midwestern Section of American Federation for Clinical Research, Thorne Hall, Northwestern University, and Drake Hotel, Chicago, Nov. 3. Dr. Robert J. Glaser, Barnes Hospital, St. Louis 10, Secretary.

Mississippi Valley Trudeau Society, Hotel Savery, Des Moines, Iowa, Oct. 14. Dr. Harold G. Curtis, Sunny Acres, Cuyahoga County Tuberculosis Hospital, Cleveland 22, Chairman, Program Committee.

National Association for Mental Health, Indianapolis, Nov. 4-6. Mr. Robert M. Heininger, 1790 Broadway, New York 19, Director.

Oklahoma City Clinical Society Conference, Oklahoma City, Oct. 24-27. Dr. Charles E. Leonard, 512 Medical Arts Bldg., Oklahoma City 2, Secretary.

Omaha Mid-West Clinical Society, Hotel Paxton, Omaha, Oct. 24-27. Mrs. Anne K. Ramsey, 1031 Medical Arts Bldg., Omaha 2, Executive Secretary.

Regional Meetings, American College of Physicians:

- Buffalo, N. Y., Oct. 14. Dr. John H. Talbot, 100 High St., Buffalo 3, N. Y., Governor.
- Madison, Wis., Oct. 15. Dr. Frederick W. Madison, 425 East Wisconsin Ave., Milwaukee 2, Governor.
- Louisville, Ky., Nov. 5. Dr. Sam A. Overstreet, 332 West Broadway, Louisville, Ky., Governor.
- Newark, N. J., Nov. 9. Dr. Edward C. Klein Jr., 6 S. Kingsman Rd., South Orange, N. J., Governor.
- Detroit, Dec. 3. Dr. H. Marvin Pollard, 1313 East Ann St., Ann Arbor, Mich., Governor.
- Hot *Springs*, Ark., Dec. 3. Dr. A. A. Blair, 100 S. 14th St., Ft. Smith, Ark., Governor.

Society of Clinical Surgery, Hotel Roosevelt, New Orleans, Nov. 11-12. Dr. Frank F. Allbritten Jr., University of Kansas Medical Center, Kansas City, Mo., Secretary.

Southern Medical Association, Shamrock Hotel, Houston, Texas, Nov. 14-17. Mr. V. O. Foster, 1020 Empire Bldg., Birmingham 3, Ala., Secretary-Manager.

Southern Society of Cancer Cytology, Houston, Texas, Nov. 14-17. Dr. J. Ernest Ayre, 1155 N.W. 14th St., Miami, Fla., Secretary.

Southwestern Medical Association, Westward Ho Hotel, Phoenix, Ariz., Nov. 16-18. Dr. Celso C. Stapp, 800 Montana St., El Paso, Texas, Secretary.

State Medical Journal Conference, Chicago, Nov. 7-8. Mr. Alfred J. Jackson, 535 N. Dearborn St., Chicago 10, Director.

The Constantinian Society, Sheraton-Park Hotel, Washington, D. C., Oct. 26-29. Dr. C. F. Shook, P. O. Box 1035-36, Toledo 1, Ohio, Secretary.

Virginia, Medical Society of, Hotel Jefferson, Richmond, Oct. 16-19. Mr. Robert I. Howard, 105 West Franklin St., Richmond, Executive *Secretary.*

Western Orthopedic Association, The Reef, Honolulu, Hawaii, Nov. 7-10. Dr. Ivar J. Larsen, 1133 Punchbowl, Honolulu 13, Hawaii, Secretary.

Western Society of Electro-Encephalography, Westward Ho Hotel, Phoenix, Ariz., Nov. 10-12. Dr. Sylvester N. Berens, 902 Boren Ave., Seattle, Secretary.

Western Surgical Association, Olympic Hotel, Seattle, Dec. 1-3. Dr. John T. Reynolds, 612 N. Michigan Blvd., Chicago 11, Secretary.

FOREIGN AND INTERNATIONAL

Conference of International Union for Health Education of the Public, Rome, Italy, Apr. 27-May 5, 1956. Mr. Lucien Viborel, 92 rue St. Denis, Paris 1^{er}, France, Secretary-General.

Congress of International Association of Limnology, Helsinki, Finland, July 26-Aug. 7, 1956. For information address: Dr. H. Luther, Snellmansgatan 16 C 36, Helsinki, Finland.

Congress of International Association of Logopedics and Phoniatrics, Barcelona, Spain, Sept. 3-7, 1956. Dr. J. Perello, Provenza 319, Barcelona 9, Spain, Secretary-General.

Congress of International Society of Hematology, Hotel Statler, Boston, Mass., U.S.A., Sept. 3-8, 1956. Dr. W. C. Moloney, 39 Bay State Road, Boston, Mass., U.S.A., Secretary.

Congress of International Society for Research on Anesthesia, Miami Beach, Fla., U.S.A., Mar. 12-15, 1956. For information write: Dr. R. J. Whitacre, 13951 Terrace Road, Cleveland 12, Ohio, U. S. A.

Congress of Latin Society of Ophthalmology, Madrid, Spain, April 24-28, 1956. For information address: Dr. Costi, Montalban 3, Madrid, Spain.

European Congress of Allergology, Florence, Italy, May 1956. Prof. Umberto Serafini, Largo della Gancia 5, Rome, Italy, Secretary-General.

European Symposium on Vitamin B_{12}, Hamburg, Germany, May 1956. For information write: Doz. Dr. H. Bauer, Nervenklinik, Hamburg-Eppendorf, Germany.

International Academy of Legal and Social Medicine, Plenary Conference, Genoa, Italy, Oct. 13-17. Prof. Domenico Macaggi, Institut de Medicine legale, Universite de Genes, Genes, Italy, President.

International Academy of Pathology, Cincinnati, Ohio, U. S. A., April 24-25, 1956. Dr. F. K. Mostofi, Armed Forces Institute of Pathology, Washington 25, D. C., U. S. A., Secretary.

International Colloquium on Chlorpromazine and Neuroleptic Agents in Psycotherapy, Ste Anne Clinic of Mental Diseases, Paris, France, Oct. 20-22. Prof. Jean Delay, College of Medicine of Paris, 1, rue Cabanio, Paris 14e, France, Chairman.

International Congress Against Alcoholism, Istanbul, Turkey, Sept. 10-15, 1956. For information address: International contre l'Alcoolisme, Case Gare 49, Lausanne, Switzerland.

International Congress of Allergology, Rio de Janeiro, Brazil, S. A., Nov. 6-13. Dr. Bernard N. Halpern, 197 boulevard St. Germain, Paris 7^{e}, France, Secretary General.

International Congress of Anthropological and Ethnological Sciences, Philadelphia, Pa., U. S. A., Sept. 2-9, 1956. Dr. William N. Fenton, National Research Council, Division of Anthropology and Psychology, 2101 Constitution Avenue, Washington 25, D. C., U. S. A., Secretary-General.

International Congress on Diseases of the Chest, Cologne, Germany, Aug. 19-23, 1956. Mr. Murray Kornfeld, 112 East Chestnut St., Chicago 11, Illinois, U. S. A., Executive Director.

International Congress of Gastroenterology, London, England, July 18-21, 1956. Mr. Hermon Taylor, London Hospital, White Chapel, London E.1, England, Honorable Secretary.

International Congress for the History of Science, Florence and Milan, Italy, Sept. 3-10, 1956. Dr. M. L. Bonelli, Instituto di Ottica, Arcetri, Florence, Italy, Secretary-General.

International Congress of Hydatid Disease, Athens, Greece, Sept. 14-18, 1956. Prof. B. Kourias, Croix-Rouge Hellenique, 1 rue Mackenzie King, Athens, Greece, Secretary-General.

International Congress of Internal Medicine, Madrid, Spain, Sept. 19-23, 1956. Dr. J. C. De Oya and Dr. J. Gimena, Hostaleza No. 90, Madrid, Spain, Secretaries.

International Congress of International College of Surgeons, Palmer House, Chicago, Illinois, U. S. A., Sept. 9-13, 1956. Dr. Max Thorek, 1516 Lake Shore Drive, Chicago, Illinois, U. S. A., Secretary-General.

International Congress of International Society of Bronchoesophagology, Buenos Aires, Argentina, S. A., Oct. 28-29. Dr. Juan Carlos Arauz, Cangallo 4015, Buenos Aires, Argentina, S. A., Secretary General.

International Congress of Neo-Hippocratic Medicine, Montecatini, Terme, Italy, May 20-22, 1956. Prof. P. Delore, 13 rue Jarente, Lyon, France, Secretary-General.

International Congress of Paediatrics, Copenhagen, Denmark, July 22-27, 1956. Professor P. Plum, Rigshospitalet, Copenhagen, Denmark, President.

International Congress of Physical Medicine, Copenhagen, Denmark, August 20-24, 1956. Dr. B. Strandberg, Kobenhavns amts sygehus i Gentofte, Dept. of Rheumatology and Physical Medicine, Hellerup, Denmark, Honorable Secretary.

International Congress of Radiology, Mexico, D. F., Mexico, July 22-28, 1956. Dr. Jose Noriega, Tepic 126 (2e piso), Mexico, D. F. 7, Mexico, Secretary General.

International Congress of World Confederation for Physical Therapy, New York, New York, U. S. A., June 17-23, 1956. For information address: Miss Mildred Elson, American Physical Therapy Association, 1790 Broadway, New York 19, New York, U. S. A.

International General Medical Congress, University of Rosario Medical College, Rosario, Argentina, S. A., Nov. 7-12. Dean Jose Imhoff, Santa Fé 3100, Rosario, Argentina, S. A., Chairman.

International Physiological Congress, Brussels, Belgium, July 29-Aug. 5, 1956. For information address: Prof. J. Reuse, Faculte de Medicine et de Pharmacie, 115 Boulevard de Waterloo, Brussels, Belgium.

International Professional Union of Gynecologists and Obstetricians, Madrid, Spain, Sept. 28-29, 1956. Dr. Jacques Courtois, 1 rue Racine, St-Germain-en-Laye (S and O), France, Permanent International Secretary-General.

Latin American Congress of Pathology, Mexico, D. F., Mexico, Dec. 11-17. For information address: Laboratorio de Anatomia Patologica, Instituto N. de Cardiologia, Avenida Cuauhtemoc 300, Mexico 7, D. F., Mexico.

North Queensland Medical Conference, Cairns, North Queensland, Australia, June 25-30, 1956. Dr. W. R. Horsfall, P.O Box 672, Cairns, N.Q., Australia, Secretary.

Pan American Congress of International College of Surgeons, Mendoza City, Argentina, S. A., Oct. 22-26. For information address: Secretary, Caseros Av. 2154, Buenos Aires, Argentina, S. A.

Pan American Congress of Ophthalmology, Santiago, Chile, S. A., Jan. 9-14, 1956. Dr. Rene Contardo, Huerfanos 930, Of. 74, Santiago, Chile, Secretary General.

Pan American Medical Social Convention, Bogota, Colombia, S. A., Oct. 15-22. Dr. Leopoldo E. Araujo, Avenida de los Presidentes Num. 506, Apartado 2589, La Habana, Cuba, Secretary.

Pan American Medical Women's Alliance, Santiago, Chile, March 6-13, 1956. For information address: Dr. Eva Cutright, 458 Beall Ave., Wooster, Ohio, U. S. A.

Venezuelan Congress of Medical Sciences, Caracas, Venezuela, S. A., Nov. 18-26. Dr. A. L. Briceno Rossi, Apartado 4412, Ofic. del Este, Caracas, Venezuela, S. A., Secretary General.

World Congress on Fertility and Sterility, Naples, Italy, May 18-26, 1956. For information address: Prof. G. Tesauro, S. Andrea della Dame, 19, Naples, Italy.

EXAMINATIONS AND LICENSURE

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: Various Centers. April 24-25 (Part II); June 19-20 (Parts I and II); September 4-5 (Part I). Candidates may file applications at any time but they must be received at least six weeks before the date of the examination for which application is made. New candidates should apply by formal registration; registered candidates may notify the board, indicating desired location, date and candidate number. Ex. Sec., Dr. John P. Hubbard, 133 South 36th St., Philadelphia 4.

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 19-21. Sec., Dr. D. G. Gill, State Office Bldg., Montgomery.

Arizona:* *Examination.* Phoenix, Oct. 12-14. *Reciprocity.* Phoenix, Oct. 15. Exec. Sec., Mr. Robert Carpenter, 411 Security Bldg., Phoenix.

Arkansas:* *Examination.* Little Rock, Nov. 10-11. Sec., Dr. Joe Verser, Harrisburg.

California: *Written.* Sacramento, Oct. 17-20. *Oral and Clinical Examinations for Foreign Medical School Graduates.* San Francisco, Nov. 13. *Oral Examination for Reciprocity Applications.* San Francisco, Nov. 12. Sec., Dr. Louis E. Jones, Room 536, 1020 N St., Sacramento.

Colorado:* *Examination.* Denver, Dec. 6-7. Final date for filing application is Nov. 4. *Reciprocity.* Denver, Oct. 11. Final date for filing application is Sept. 12. Exec. Sec., Mrs. Beulah H. Hudgens, 831 Republic Bldg., Denver 2.

Connecticut:* *Regular. Examination.* Hartford, Nov. 8-10. Sec., Dr. Creighton Barker, 160 St. Ronan St., New Haven. *Homeopathic.* Derby, Nov. 8-19. Sec., Dr. Donald A. Davis, 38 Elizabeth St., Derby.

Delaware: *Examination.* Dover, Jan. 10-12. *Reciprocity.* Dover, Jan. 19. Sec., Dr. Joseph S. McDaniel, Dover.

Florida:* *Examination.* Miami Beach, Nov. 20-21. Sec., Dr. Homer L. Pearson, 901 N. W. 17th St., Miami.

Idaho: *Examination and Reciprocity.* Boise, Jan. 9-11. Exec. Sec., Mr. Armand L. Bird, 364 Sonna Bldg., Boise.

Illinois: *Examination and Reciprocity.* Chicago, Oct. 11-13. Supt. of Registration, Mr. Fredric B. Selcke, State House, Springfield.

Indiana: *Examination.* Indianapolis, June. Exec. Sec., Miss Ruth V. Kirk, 538 K. of P. Bldg., Indianapolis.

Iowa:* *Examination.* Des Moines, Dec. 5-7. Ex. Sec., Mr. Ronald V. Saf, State Office Bldg., Des Moines.

Kansas: *Examination and Endorsement.* Topeka, Dec. 7-8. Sec., Dr. Lyle F. Schmaus, New Brotherhood Bldg., Kansas City.

Kentucky: *Examination.* Louisville, Dec. 5-7. Asst. Sec., Mr. R. F. Dixon, 620 S. 3rd St., Louisville.

Maine: *Examination and Reciprocity.* Portland, Nov. 8-9. Sec., Dr. Adam P. Leighton, Portland.

Maryland: *Examination.* Baltimore, Dec. 13-16. Exec. Sec., Miss Hannah A. McCarthy, 1215 Cathedral St., Baltimore 1.

Michigan:* *Examination.* Lansing, Oct. 12-14. Sec., Dr. J. Earl McIntyre, 118 Stevens T. Mason Bldg., Lansing.

Minnesota:* *Examination and Reciprocity.* Minneapolis, Oct. 18-20. Sec., Dr. F. H. Magney, 230 Lowry Medical Arts Bldg., St. Paul 2.

Mississippi: *Reciprocity.* Jackson, December. Asst. Sec., Dr. R. N. Whitfield, State Board of Health, Jackson.

Missouri: *Examination and Endorsement.* St. Louis, Oct. 21-22. Exec. Sec., Mr. John A. Hailey, Box 4, State Capitol Bldg., Jefferson City.

Nebraska:* *Examination.* Omaha, June 18-20. Director, Bureau of Examining Boards, Mr. Husted K. Watson, 1009 State Capitol Bldg., Lincoln.

GOVERNMENT SERVICES

ARMY

Personal.—Col. Dwight M. Kuhns has been named deputy director of the Armed Forces Institute of Pathology.——Col. Bryan C. T. Fenton has been appointed chief of the supply division in the office of the surgeon general, replacing Col. Jenner G. Jones, who has been assigned to the Armed Services Medical Procurement Agency, Brooklyn, N. Y.——Dr. Theodor Wagner-Jauregg has resigned from his position as chief, medicinal chemistry branch, Chemical Corps Medical Laboratories, Army Chemical Center, Md., and will accept a position as chief of the chemical laboratories of the pharmaceutical firm of B. Siegfried, A. G., Zofingen, Switzerland. Dr. Wagner-Jauregg is one of a group of three scientists who came from Germany in 1948 to work for the Chemical Corps. The other two scientists, Dr. Hans J. Trurnit, Medical Laboratories, and Dr. F. W. Hoffman, Chemical and Radiological Laboratories, have become United States citizens.

ATOMIC ENERGY COMMISSION

Research Contracts Announced by AEC.—Award of 175 unclassified life science research contracts in biology, medicine, biophysics, and radiation instrumentation was announced Sept. 6 by the Atomic Energy Commission. The contracts were awarded to universities and private institutions as part of the AEC's policy of assisting and fostering research and development in fields related to atomic energy as specified in the Atomic Energy Acts of 1946 and 1954. Thirty-three of the awards, each for one year, are new projects. Sixteen are in biology, 15 in medical sciences, one in biophysics, and one in radiation instrumentation. One hundred forty-two contract renewals for one year were awarded to allow for continuation of research already in progress. Seventy-nine of these are in biology, 53 in medical sciences, 8 in biophysics, and 2 in radiation instrumentation.

SELECTIVE SERVICE SYSTEM

Processing of Physicians for Military Service.—The Selective Service System on Sept. 1 issued the following bulletin in order to provide an adequate pool of new graduates classified in 1-A to meet the calls by the armed forces for physicians and dentists during the fiscal year 1956: 1. Those physicians who have just completed their internships and recent graduates of dental colleges should be made available to fill special calls in accordance with the regulations as soon as possible. There should be no need for filling anticipated special calls with any special registrants except those of priorities 1 and 2 and the younger registrants of priority 3. 2. Local boards are requested to expedite the classification and physical examination of priority 1 and 2 physicians and dentists and of the younger physicians and dentists of priority 3. 3. Local boards are also requested to expedite the processing of physicians and dentists toward induction as regular registrants in accordance with the provisions of Operations Bulletin No. 88, as amended.

PUBLIC HEALTH SERVICE

Cancer Information Institute.—The National Cancer Institute will conduct a one day Cancer Information Institute for public and parochial secondary school teachers of general science, biology, chemistry, and physics. The institute will be held on Saturday, Oct. 15, in the clinical center of the National Institutes of Health in Bethesda, Md. The program is planned to be of interest and utility to science teachers. A short introduction to the cancer problem will be presented by three National Cancer Institute staff members. Next will be a description of demonstrations, projects, and experiments that will be capable of reproduction in the classroom for assignment to brighter pupils or for extracurricular science club activities. Luncheon may be had in the clinical center cafeteria. Tables will be marked so that teachers with similar interests may meet with staff research specialists. After lunch, teachers will go in small groups to laboratories to meet with research scientists and technicians, examine the laboratory facilities, and discuss teaching-demonstration problems. The last activity of the day will be a panel discussion on how best to bring cancer information into the year's program of study. General science, biology, physics, and chemistry will be represented on this panel. A question-and-answer period will follow.

Grants for Research in Nursing.—Research grants and fellowships in the field of nursing will be available from the Public Health Service in the fiscal year that began July 1, Surgeon General Leonard A. Scheele announced. A total of $625,000 was appropriated by Congress for this purpose. This program is designed to support investigations into ways and means of improving quality of nursing care, training nurses in research methods applicable to nursing problems, and making better use of the limited supply of professional nurses. The grants in most cases will be made directly to universities, hospitals, health agencies, or professional groups, under whose auspices the research projects will be carried out.

The research fellowships will be offered only to nurses for the purpose of receiving special postgraduate training in research methods. Fellowships may be used for graduate research study in universities or for research training provided by any health agency or research center. To be accepted for a fellowship, a nurse must be sponsored by the university or agency where the training will be given. Applications may be submitted to the Division of Research Grants, National Institutes of Health, Bethesda 14, Md.

VETERANS ADMINISTRATION

Personal.—Dr. Paul M. Ireland, presently director of surgical service in the central VA office in Washington, D. C., has been appointed manager of the VA hospital in Ann Arbor, Mich.——Dr. Claud E. Carter, presently manager of the VA hospital in Fort Bayard, N. Mex., has been appointed manager of the VA hospital at Butler, Pa.——Dr. Charles S. Livingston, presently manager of the VA hospital at Butler, Pa., has been appointed manager of the VA hospital at Batavia, N. Y.

MISCELLANEOUS

New Radiochemistry Laboratory.—A new radiochemistry laboratory for preparing and distributing standard samples of radioactive materials has been established at the National Bureau of Standards. The resources of this laboratory are expected to expedite greatly the bureau's program of radioactive sample distribution. As custodian of the nation's standards of radioactivity, the National Bureau of Standards carries on a broad research and development program aimed at producing the radioactive standards required by the medical, scientific, and commercial users of radioactive materials. The new radiochemistry laboratory is one of six related facilities that have been established at the bureau to provide this service. The other five consist of laboratories for performing alpha-ray measurements, radioisotope standardization, nuclear spectroscopy, radon testing, and gamma-ray measurements. The radiochemistry laboratory is primarily responsible for the preparation, maintenance, and distribution of about 57 different radioactive nuclides and ores. Included in this group are carbon-14, sodium-22, phosphorus-32, cobalt-60, iodine-131, and gold-198. New uses for these and other nuclides in industry, physics, and medical research and therapy have increased tremendously the demand for standard samples of radioactivity. The program of the radiochemistry laboratory is expected to increase steadily as a result of the expanding uses of radioisotopes in medicine and as biological and industrial tracers. Further work is expected on the program to intercompare radioactive standards and methods of measurement with Canada and Great Britain and other countries. It is planned that international standards of a number of nuclides be established, beginning with phosphorus-32 and cobalt-60.

NEW JERSEY: *Examination.* Trenton, Oct. 18-21. Sec., Dr. Patrick H. Corrigan, 28 W. State St., Trenton.
NEW MEXICO:* *Examination and Reciprocity.* Santa Fe, Nov. 21-22. Sec., Dr. R. C. Derbyshire, 227 E. Palace Ave., Santa Fe.
NEW YORK: *Examination.* Albany, Buffalo, New York City and Syracuse, Oct. 4-7. Sec., Dr. Stiles D. Ezell, 23 S. Pearl St., Albany.
NORTH CAROLINA: *Reciprocity.* Asheville, Oct. 31. Sec., Dr. Jos. J. Combs, 716 Professional Bldg., Raleigh.
NORTH DAKOTA: *Examination.* Grand Forks, Jan. 4-6. *Reciprocity.* Grand Forks, Jan. 7. Sec., Dr. C. J. Glaspel, Box 228, Grafton.
OHIO: *Reciprocity.* Columbus, Oct. 4. *Examination.* Columbus, Dec. 15-17. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.
OKLAHOMA:* *Examination.* Oklahoma City, June 5-6. Sec., Dr. E. F. Lester, 813 Braniff Bldg., Oklahoma City.
OREGON:* *Reciprocity.* Portland, Oct. 13-15. *Examination.* Portland, January. Sec., Mr. Howard I. Bobbitt, 609 Failing Bldg., Portland.
PENNSYLVANIA: *Examination.* Philadelphia, January. Acting Sec., Miss Marguerite G. Steiner, Box 911, Harrisburg.
SOUTH CAROLINA: *Examination.* Columbia, Nov. 7. Sec., Mr. N. B. Heyward, 1329 Blanding St., Columbia.
SOUTH DAKOTA:* *Examination.* Sioux Falls, Jan. 17-18. Exec. Sec., Mr. John C. Foster, 300 First National Bank Bldg., Sioux Falls.
TEXAS:* *Examination and Reciprocity.* Galveston, Dec. 1-3. Sec., Dr. M. H. Crabb, 1714 Medical Arts Bldg., Fort Worth 2.
VIRGINIA: *Examination.* Richmond, Dec. 7-9. *Reciprocity.* Richmond, Dec. 6. Final date for filing application is Nov. 21. Address the Secretary, 631 First St. S.W., Roanoke.
WEST VIRGINIA: *Reciprocity.* Charleston, Oct. 10. Sec., Dr. N. H. Dyer, Charleston 5.
WISCONSIN:* *Reciprocity.* Madison, Oct. 21; *Reciprocity and Examination.* Madison, Jan. 10-12; *Reciprocity.* Madison, Spring; *Reciprocity and Examination.* Milwaukee, July 10-12. Sec., Dr. Thomas W. Tormey, Jr., 1140 State Office Bldg., Madison.
ALASKA:* On application. Sec., Dr. W. M. Whitehead, 172 South Franklin St., Juneau.
GUAM: The Commission on Licensure will meet whenever a candidate appears or submits his credentials. Sec., Dr. John E. Kennedy, Agana.
HAWAII: *Examination.* Honolulu, Jan. 9-12. Sec., Dr. I. L. Tilden, 1020 Kapiolani, St., Honolulu.
VIRGIN ISLANDS: *Examination and Endorsement.* St. Thomas, Nov. 8-9. Sec., Dr. Earle M. Rice, St. Thomas.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

DISTRICT OF COLUMBIA: *Examination.* Washington, Oct. 24-25. Deputy, Mr. Paul Foley, 1740 Massachusetts Ave., N.W., Washington 6.
FLORIDA: *Examination.* Gainesville, Nov. 5. Sec., Mr. M. W. Emmel, Box 340, Gainesville.
IOWA: *Examination.* Des Moines, Oct. 11. Sec., Mr. Ben H. Peterson, Coe College, Cedar Rapids.
MICHIGAN: *Examination and Endorsement.* Detroit and Ann Arbor, Oct. 14-15. Sec., Mrs. Anne Baker, 410 W. Michigan Ave., Lansing 15.
OREGON: *Examination.* Portland, Dec. 3. Sec., Mr. Charles D. Byrne, State Board of Higher Education, Eugene.
SOUTH DAKOTA: *Examination.* Vermillion, Dec. 2-3. Sec., Dr. Gregg M. Evans, 310 E. 15th St., Yankton.
TEXAS: *Examination.* Austin and Houston, Oct. 21-22. Sec., Brother Raphael Wilson, 407 Perry-Brooks Bldg., Austin.
ALASKA: On application. Juneau or other towns in Territory as decided by Board. *Reciprocity.* On application. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

---

*Basic Science Certificate required.

MAGAZINE–TELEVISION REPORT

The following list of current medical articles in mass-circulation magazines and forthcoming network television programs on medical subjects is published each week only for the information of readers of THE JOURNAL. *Unless specifically stated, the American Medical Association neither approves nor disapproves of the articles and programs reported.*

TELEVISION

Monday, Oct. 10

NBC-TV, 9 p. m. EDT. "Medic" features a story on medicine's fight against asthma and hay fever entitled "A Room, A Boy and Mr. Bodine."

ABC-TV, 9:30 p. m. EDT. "Medical Horizons" reports on an artificial kidney that takes over renal function during acute emergencies associated with kidney shutdown. Telecast remote from Georgetown University Hospital, Washington, D. C., in cooperation with the American Medical Association.

Wednesday, Oct. 12

NBC-TV, 11:30 a. m. EDT. "Medical and Health News with Howard Whitman," a segment of the "Home" program.

Sunday, Oct. 16

NBC-TV, 3 p. m. EDT. "Dr. Spock," featuring Dr. Benjamin Spock, provides information on child care and development.

Monday, Oct. 17

ABC-TV, 9:30 p. m. EDT. "Medical Horizons" goes to University of Pennsylvania School of Medicine for a program on the training of a medical student.

MAGAZINES

The American Weekly, Oct. 9, 1955

"The Case for the Smoker," by William Engle

The author shows "why some noted cancer experts are not convinced by the reports (that there is a cause and effect relationship between cigarette smoking and lung cancer)."

Parade, Oct. 9, 1955

"Children's Ward: No Place for Tears," by John Devaney

A picture-text story of the children's wards at Johns Hopkins Hospital.

Parents' Magazine, October, 1955

"A Baby's Best Friend Is His Doctor," by Paulette Kahn Hartrich

A list of instructions to mother showing what she should do in order to make her doctor's services more valuable.

"The Truth About Miscarriage," by Alan F. Guttmacher, M.D.

A discussion of abortion and its cause. Treatment for chronic aborters reported by the author include dietary instructions plus thyroid, stilbesterol and progesterone, and psychotherapy plus liberal amounts of vitamins B and C.

Woman's Home Companion, October, 1955

"What's It Worth to Keep Your Child Well?" by Milton J. E. Senn, M.D.

"Both doctors and parents are developing a brand-new conception of the health job." The author tells what a doctor looks for during formative years and what he expects of the parents.

Coronet, October, 1955

"Improve Your Sight Without Glasses," by Lawrence Galton

"Miss Clara A. Hackett . . . has added many techniques to increase the effectiveness of the original Bates (Dr. William A. Bates) methods." The article tells of the success of these techniques for improving eyesight and describes some "major" exercises.

Cosmopolitan, October, 1955

"Witch Doctors and Your Health," by George W. Groh

Medicine scouts employed by major pharmaceutical houses are tracking down tribal remedies in Africa and South America. "Some of these drugs are natural medicines which we can take over without essential change. Others are deadly poisons—the weapon drugs of jungle warriors—which we can adapt to purposes quite different from the native use."

"New Help for Your Skin," by Lawrence Galton

The author lists these "new" treatments for skin diseases: fludrocortisone ointment for eczema; beams of high-energy electrons for atopic dermatitis, disseminated neurodermatitis, and exfoliative dermatitis; high-frequency electric current for acne; grenz rays for psoriasis; and procaine as an anesthetic in scar planing.

Saturday Evening Post, Oct. 1, 1955

"Are Patients Human Beings?" by Milton Silverman

Hospital people are finding they must take care of the "whole man" and "provide warmth, comfort and friendship as well as efficiency in American hospitals." The author reports that "smart hospitals are junking traditional but boneheaded customs like 5 a. m. reveille and payment in advance."

GOVERNMENT SERVICES

ARMY

Personal.—Col. Dwight M. Kuhns has been named deputy director of the Armed Forces Institute of Pathology.——Col. Bryan C. T. Fenton has been appointed chief of the supply division in the office of the surgeon general, replacing Col. Jenner G. Jones, who has been assigned to the Armed Services Medical Procurement Agency, Brooklyn, N. Y.——Dr. Theodor Wagner-Jauregg has resigned from his position as chief, medicinal chemistry branch, Chemical Corps Medical Laboratories, Army Chemical Center, Md., and will accept a position as chief of the chemical laboratories of the pharmaceutical firm of B. Siegfried, A. G., Zofingen, Switzerland. Dr. Wagner-Jauregg is one of a group of three scientists who came from Germany in 1948 to work for the Chemical Corps. The other two scientists, Dr. Hans J. Trurnit, Medical Laboratories, and Dr. F. W. Hoffman, Chemical and Radiological Laboratories, have become United States citizens.

ATOMIC ENERGY COMMISSION

Research Contracts Announced by AEC.—Award of 175 unclassified life science research contracts in biology, medicine, biophysics, and radiation instrumentation was announced Sept. 6 by the Atomic Energy Commission. The contracts were awarded to universities and private institutions as part of the AEC's policy of assisting and fostering research and development in fields related to atomic energy as specified in the Atomic Energy Acts of 1946 and 1954. Thirty-three of the awards, each for one year, are new projects. Sixteen are in biology, 15 in medical sciences, one in biophysics, and one in radiation instrumentation. One hundred forty-two contract renewals for one year were awarded to allow for continuation of research already in progress. Seventy-nine of these are in biology, 53 in medical sciences, 8 in biophysics, and 2 in radiation instrumentation.

SELECTIVE SERVICE SYSTEM

Processing of Physicians for Military Service.—The Selective Service System on Sept. 1 issued the following bulletin in order to provide an adequate pool of new graduates classified in 1-A to meet the calls by the armed forces for physicians and dentists during the fiscal year 1956: 1. Those physicians who have just completed their internships and recent graduates of dental colleges should be made available to fill special calls in accordance with the regulations as soon as possible. There should be no need for filling anticipated special calls with any special registrants except those of priorities 1 and 2 and the younger registrants of priority 3. 2. Local boards are requested to expedite the classification and physical examination of priority 1 and 2 physicians and dentists and of the younger physicians and dentists of priority 3. 3. Local boards are also requested to expedite the processing of physicians and dentists toward induction as regular registrants in accordance with the provisions of Operations Bulletin No. 88, as amended.

PUBLIC HEALTH SERVICE

Cancer Information Institute.—The National Cancer Institute will conduct a one day Cancer Information Institute for public and parochial secondary school teachers of general science, biology, chemistry, and physics. The institute will be held on Saturday, Oct. 15, in the clinical center of the National Institutes of Health in Bethesda, Md. The program is planned to be of interest and utility to science teachers. A short introduction to the cancer problem will be presented by three National Cancer Institute staff members. Next will be a description of demonstrations, projects, and experiments that will be capable of reproduction in the classroom for assignment to brighter pupils or for extracurricular science club activities. Luncheon may be had in the clinical center cafeteria. Tables will be marked so that teachers with similar interests may meet with staff research specialists. After lunch, teachers will go in small groups to laboratories to meet with research scientists and technicians, examine the laboratory facilities, and discuss teaching-demonstration problems. The last activity of the day will be a panel discussion on how best to bring cancer information into the year's program of study. General science, biology, physics, and chemistry will be represented on this panel. A question-and-answer period will follow.

Grants for Research in Nursing.—Research grants and fellowships in the field of nursing will be available from the Public Health Service in the fiscal year that began July 1, Surgeon General Leonard A. Scheele announced. A total of $625,000 was appropriated by Congress for this purpose. This program is designed to support investigations into ways and means of improving quality of nursing care, training nurses in research methods applicable to nursing problems, and making better use of the limited supply of professional nurses. The grants in most cases will be made directly to universities, hospitals, health agencies, or professional groups, under whose auspices the research projects will be carried out.

The research fellowships will be offered only to nurses for the purpose of receiving special postgraduate training in research methods. Fellowships may be used for graduate research study in universities or for research training provided by any health agency or research center. To be accepted for a fellowship, a nurse must be sponsored by the university or agency where the training will be given. Applications may be submitted to the Division of Research Grants, National Institutes of Health, Bethesda 14, Md.

VETERANS ADMINISTRATION

Personal.—Dr. Paul M. Ireland, presently director of surgical service in the central VA office in Washington, D. C., has been appointed manager of the VA hospital in Ann Arbor, Mich.——Dr. Claud E. Carter, presently manager of the VA hospital in Fort Bayard, N. Mex., has been appointed manager of the VA hospital at Butler, Pa.——Dr. Charles S. Livingston, presently manager of the VA hospital at Butler, Pa., has been appointed manager of the VA hospital at Batavia, N. Y.

MISCELLANEOUS

New Radiochemistry Laboratory.—A new radiochemistry laboratory for preparing and distributing standard samples of radioactive materials has been established at the National Bureau of Standards. The resources of this laboratory are expected to expedite greatly the bureau's program of radioactive sample distribution. As custodian of the nation's standards of radioactivity, the National Bureau of Standards carries on a broad research and development program aimed at producing the radioactive standards required by the medical, scientific, and commercial users of radioactive materials. The new radiochemistry laboratory is one of six related facilities that have been established at the bureau to provide this service. The other five consist of laboratories for performing alpha-ray measurements, radioisotope standardization, nuclear spectroscopy, radon testing, and gamma-ray measurements. The radiochemistry laboratory is primarily responsible for the preparation, maintenance, and distribution of about 57 different radioactive nuclides and ores. Included in this group are carbon-14, sodium-22, phosphorus-32, cobalt-60, iodine-131, and gold-198. New uses for these and other nuclides in industry, physics, and medical research and therapy have increased tremendously the demand for standard samples of radioactivity. The program of the radiochemistry laboratory is expected to increase steadily as a result of the expanding uses of radioisotopes in medicine and as biological and industrial tracers. Further work is expected on the program to intercompare radioactive standards and methods of measurement with Canada and Great Britain and other countries. It is planned that international standards of a number of nuclides be established, beginning with phosphorus-32 and cobalt-60.

DEATHS

Peterson, Carl Melancton ⊕ Chicago; born in Rockford, Ill., Dec. 6, 1899; University of Minnesota Medical School, Minneapolis, 1927; in private practice from 1927 to 1930, when he became staff associate of the Council on Medical Education and Hospitals of the American Medical Association; since 1938 has served as Secretary of its Council on Industrial Health; specialist certified by the American Board of Preventive Medicine; member of the medical committee, Industrial Hygiene Foundation, small business committee of the National Safety Council, medical advisory board, Welfare and Retirement Fund, United Mine Workers of America, medical committee and executive committee of the President's Committee on Employment of the Physically Handicapped, medical advisory council, American Association of Industrial Nurses, expert advisory panel on occupational health, World Health Organization, United States committee, International Congress of Industrial Medicine, and the committee for industry, Industrial Council for Tropical Health; member of the board of directors and research committee of the Midwestern Air Pollution Prevention Association, Inc.; member of the rehabilitation committee of the council on community service and education of the American Heart Association, the committee on industrial health of the Illinois State Medical Society, and the advisory committee to the literature abstract service for industrial medicine of the Illinois Society for Mental Health, Inc.; chairman of the international committee on occupational health services of the World Medical Association; member of the medical advisory committee of the Common Cold Foundation and of the publication committee of the American Academy of General Practice; chairman of the committee on industrial health and rehabilitation of the Chicago Heart Association; served as chairman on the subcommittee on occupational medicine of the Institute of Medicine of Chicago; member of the American Industrial Hygiene Association; fellow of the American Public Health Association, American Academy of Occupational Medicine, American Academy of Compensation Medicine, and the Industrial Medical Association; member of the editorial board of the *Archives of Industrial Health*; died in the Margaret R. Pardee Memorial Hospital in Hendersonville, N. C., Sept. 27, aged 55, as the result of injuries received in an airplane crash.

Adams, James Harlan ⊕ Wichita, Kan.; Kansas City (Mo.) Hahnemann Medical College, 1914; died Aug. 17, aged 80, of carcinoma of the prostate.

Adams, William Alfred ⊕ Akron, Colo.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1897; an associate member of the American Medical Association; died June 2, aged 81, of carcinoma of the prostate and coronary occlusion.

Alexander, James Ramsey ⊕ Charlotte, N. C.; University of Maryland School of Medicine, Baltimore, 1894; at one time superintendent of the Presbyterian Hospital; died July 22, aged 85, of rupture of the abdominal aorta and arteriosclerosis.

Bentley, Roy Leighton, Stanton, Mich.; University of Michigan Homeopathic Medical School, Ann Arbor, 1893; served as school director and as bank president; died Aug. 25, aged 85, of coronary occlusion.

Block, Charles ⊕ Newark, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1942; received the Bronze Star for gallantry in action during World War II; interned at the Newark Beth Israel Hospital, where he died Aug. 14, aged 39, of myocardial infarction.

Buckley, Frederick Herbert, Rochester, N. Y.; Syracuse University College of Medicine, 1914; member of the Medical Society of the State of New York; died Aug. 10, aged 69.

Cunnane, Thomas Bartholomew ⊕ Los Angeles; College of Physicians and Surgeons, Los Angeles, 1917; associate clinical professor of medicine at the University of Southern California School of Medicine; fellow of the American College of Physicians; member of the Los Angeles Heart Association; fellow of the Los Angeles Academy of Medicine; on the staff of the Good Samaritan Hospital, where he died Aug. 28, aged 60, of myocardial infarction and coronary thrombosis.

Dickens, William Mason ⊕ Waco, Texas; University of Tennessee College of Medicine, Memphis, 1911; veteran of World War I; served during World War II; formerly member of the state board of health; chief medical officer of the Veterans Administration regional headquarters in Waco; died in Brownwood July 28, aged 67, of coronary occlusion.

Eliscu, Frederick ⊕ St. Joseph, Mo.; Northwestern Medical College, St. Joseph, 1893; also a graduate in pharmacy; at one time an instructor in physical diagnosis at the Central Medical College; past-president of St. Joseph Medical Society; during World War I medical examiner for men entering military service; died in Missouri Methodist Hospital Aug. 24, aged 87.

Feldman, Samuel Hyman ⊕ Chelsea, Mass.; Tufts College Medical School, Boston, 1924; died in the Beth Israel Hospital, Boston, Aug. 10, aged 59.

Fischer, Charles ⊕ Philadelphia; Temple University School of Medicine, Philadelphia, 1914; an associate member of the American Medical Association; on the staffs of the Frankford and Episcopal hospitals, and St. Christopher's Hospital for Children; died Aug. 15, aged 75, of coronary occlusion.

George, John Henry, Lexington, Mo.; Kansas City (Mo.) Medical College, 1896; died July 27, aged 88, of senility.

Hecht, Max, Crompond, N. Y.; Long Island College Hospital, Brooklyn, 1914; died May 23, aged 69, of acute coronary thrombosis.

Kaluza, Ernst Karl, Poughkeepsie, N. Y.; Universität Heidelberg Medizinische Fakultät, Baden, Germany, 1922; on the staff of St. Francis Hospital; died June 25, aged 58, of cancer.

Lyon, William Edwin, Des Moines, Iowa; State University of Iowa College of Medicine, Iowa City, 1897; died in the Veterans Administration Hospital, Knoxville, Aug. 3, aged 83, of arteriosclerosis.

Martin, John Franklin, Latimer, Iowa; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1912; for many years mayor and county coroner of Latimer; served on the board of education; member of the staff of the Lutheran Hospital in Hampton, where he died May 3, aged 68, of myocardial infarction.

Peter, Arthur Louis, Alhambra, Calif.; Denver College of Physicians and Surgeons, 1900; served during World War I; died in Huntington Memorial Hospital, Pasadena, Calif., May 17, aged 79, of cerebral thrombosis.

Phelps, Marcus ⊕ Leitchfield, Ky.; University of Louisville Medical Department, 1907; died July 24, aged 74.

Snead, Nash P. ⊕ Cartersville, Va.; Medical College of Virginia, Richmond, 1893; died July 7, aged 81, of embolism and diabetes mellitus.

Stein, Louis Arthur ⊕ Trenton, N. J.; New York Homeopathic Medical College and Flower Hospital, New York City, 1916; on the staff of the William McKinley Hospital, where he died July 18, aged 62, of acute myocardial infarction.

Taylor, Eugene Arthur, Washington, D. C.; University of Virginia Department of Medicine, Charlottesville, 1908; member of the Medical Society of the District of Columbia; for many years on the staff of the Episcopal Eye, Ear, and Throat Hospital; died July 22, aged 71, of acute coronary thrombosis.

Thompson, Clarence George ⊕ Norwichtown, Conn.; New York Homeopathic Medical College and Flower Hospital, New York City, 1919; director of health, Norwich, Preston, and Ledyard; on the staff of the William W. Backus Hospital in Norwich, where he died May 6, aged 66, of cancer.

⊕ Indicates Member of the American Medical Association.

FOREIGN LETTERS

BRAZIL

Brucellosis and Blood Transfusions.—Brucellosis is one of the diseases that may be transmitted by a blood transfusion. Trying to determine the frequency of brucellosis in donors that come to the blood bank at the Hospital das Clinicas of the University of São Paulo, Dr. Carlos da Silva Lacaz and his co-workers performed a serologic survey (*Rev. Assoc. med. brasil.* 1:385 [July] 1955). The results of rapid and slow serum-agglutinations showed the incidence of positive reactions to be very low. The material used in these tests was from donors considered to be perfectly healthy. Using the rapid test of Huddleston and considering a titer of 1:100 significant, 9 positive reactions (1.07%) were obtained in a series of 839 donors. The slow serum agglutination test revealed only two positive reactions, or 0.2% in a titer of 1:160. The readings of serum-agglutinations after centrifugation (Hall and Manion technique) favored the development of false positive reactions. The surface fixation test of Castañeda was negative in all those on whom it was performed in titers higher than 1:40. Although the transmission of brucellosis by the transfusion of blood has been demonstrated in rare cases, the problem is of little practical interest because the disease is not common here. Even so, those who slaughter hogs, workers in refrigerators, butchers, and veterinarians, and all those with suspected brucellosis should be rejected as donors, or rapid serum-agglutination, being easy to do, should be performed on such persons in the blood banks.

Q Fever.—The first clinical case of Q fever in São Paulo is reported by Dr. L. A. Ribeiro do Valle and his co-workers in *Rev. paulista de medicina* (46:447 [June] 1955). In this patient the onset was sudden with headache, malaise, fever, productive cough, and sharp cutting pain on the left side of the chest. Later the patient complained of diarrhea, vomiting, and abdominal pain. On the 10th day of the disease, at the time of the patient's admission to the hospital, an area of slight dulness, fine crepitant rales, and increased tactile fremitus was observed at the base of his left lung. Roentgenograms taken at intervals of several days revealed the findings of an atypical pneumonia. The cause of the disease was established by serologic tests. A significant increase of the complement-fixing antibody titer for Q fever was shown by testing four patient's blood samples collected during different stages of the illness. The complement-fixing antibody titer for the viruses of the psittacosis-lymphogranuloma venereum group was constant in all the blood samples tested. The cold agglutination test was negative as well as the hemagglutination test for influenza A and B.

ENGLAND

Legal Liability in the National Health Service.—Until the introduction of the National Health Service the courts of England and Scotland held that medical practitioners should accept full responsibility in law for the treatment of their patients. Hospital physicians were not considered servants of the hospital in which they worked and were therefore also held legally responsible for their professional actions. Recently, a number of judgments in the courts has shown that this view has been radically changed. Thus, Lord President Cooper in a decision last year expressed the view that "under the new Act and regulations the obligation on the State is to treat the patient and not merely to make arrangements for his treatment by and at the sole responsibility of independent contractors." Lord Justice Denning, giving judgment in a case involving the professional actions of an orthopedist, said: "Whatever may have been the position of a consultant in former times, nowadays, since the National Health Service Act, the term 'consultant' does not denote a particular relationship between a doctor and a hospital. . . . Whether he is called a specialist or consultant makes no difference. He, like the rest of the staff, is merely carrying out the duties of the Minister." The Central Consultants and Specialists Committee of Scotland has circulated a memorandum to all medical practitioners in Scotland. The memorandum states that the National Health Service, whether by intention or not, has established a state hospital service, the medical personnel of which are now state servants in law. This raises important issues, because physicians entered into contract with the new hospital boards established by the act on the assurance that there would be no change in their relationship with the hospital authorities.

The committee states that it does not consider that hospital boards are likely to want to interfere deliberately with clinical discretion but thinks that they may be compelled to lay down rules or procedure for certain categories of medical staff as a safeguard to compensation claims by patients. To support this view the committee quotes a recent case in which legal liability for damages was assigned to the hospital authority because it had allowed a junior medical officer to give a particular anesthetic, with disastrous results. The committee thinks that any form of control on the part of hospital authorities would hamper routine hospital work and the teaching and practice of medicine in the hospitals. Once any form of control or direction is started it is hard to foresee where it would stop. Hospital records are now no longer secret and confidential. Hospital authorities require for legal purposes that medical records be submitted to their own solicitor before passing them on. At present, this incursion of the state has been limited to the sphere of the hospital, but there is no reason why this doctrine of state responsibility should not be extended to the care of patients treated under the National Health Service outside hospitals. If it did, all physicians under contract with the National Health Service would be servants of the state or of local authorities. The committee has invited the Joint Consultants Committee to endeavor to reestablish in law the previous relationship of hospital physicians to the management of hospitals in which they work. This would involve an approach to the Ministry of Health demanding legislative action. As Parliament would have to be satisfied that a change would not jeopardize a patient's legal right to damages when negligence had been proved, governmental agreement to this change would probably be conditional on all hospital medical personnel belonging to a medical protective society, or some other equivalent insurance, as a condition of employment. Although it is recognized that this almost amounts to trade unionism, its acceptance would seem justifiable. The alternative would be the surrender of professional freedom.

Radiographic Use of Edathamil.—The water-soluble chelated compound, lead sodium edathamil, has been shown by Sapeika (*Brit. M. J.* 2:167, 1955) to be of value as a contrast medium for oral and parenteral administration. Edathamil itself is a chelating agent and has been used in the treatment of poisoning by heavy metals such as lead. Results from laboratory studies suggest that lead edathamil might be of practical value for radiographic purposes in man, since dense shadows are obtained with it and its administration by intravenous injection causes no untoward side-effects in the doses likely to be required as a contrast agent. Lead sodium edathamil is soluble in water and being un-ionized does not give the usual reactions of ionized lead; it is therefore nontoxic. Oral administration allows visualization of the esophagus. Administration of 15 cc. of a 50% solution produced renal shadows within three minutes lasting for 30 to 40 minutes. The results are equal to those after use of diodone. A solution of lead sodium edathamil may also be used for visualization of the nasal sinuses, which are filled by displacement in Parkinson's lateral low head position. The lead compound does not appear to irritate the gastrointestinal tract, but, because it produces black stools, due presumably to lead sulfide, this method should be used with caution.

The items in these letters are contributed by regular correspondents in the various foreign countries.

Bentley, Roy Leighton, Stanton, Mich.; University of Michigan Homeopathic Medical School, Ann Arbor, 1893; served as school director and as bank president; died Aug. 25, aged 85, of coronary occlusion.

Block, Charles ⊕ Newark, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1942; received the Bronze Star for gallantry in action during World War II; interned at the Newark Beth Israel Hospital, where he died Aug. 14, aged 39, of myocardial infarction.

Buckley, Frederick Herbert, Rochester, N. Y.; Syracuse University College of Medicine, 1914; member of the Medical Society of the State of New York; died Aug. 10, aged 69.

Cunnane, Thomas Bartholomew ⊕ Los Angeles; College of Physicians and Surgeons, Los Angeles, 1917; associate clinical professor of medicine at the University of Southern California School of Medicine; fellow of the American College of Physicians; member of the Los Angeles Heart Association; fellow of the Los Angeles Academy of Medicine; on the staff of the Good Samaritan Hospital, where he died Aug. 28, aged 60, of myocardial infarction and coronary thrombosis.

Dickens, William Mason ⊕ Waco, Texas; University of Tennessee College of Medicine, Memphis, 1911; veteran of World War I; served during World War II; formerly member of the state board of health; chief medical officer of the Veterans Administration regional headquarters in Waco; died in Brownwood July 28, aged 67, of coronary occlusion.

Eliscu, Frederick ⊕ St. Joseph, Mo.; Northwestern Medical College, St. Joseph, 1893; also a graduate in pharmacy; at one time an instructor in physical diagnosis at the Central Medical College; past-president of St. Joseph Medical Society; during World War I medical examiner for men entering military service; died in Missouri Methodist Hospital Aug. 24, aged 87.

Feldman, Samuel Hyman ⊕ Chelsea, Mass.; Tufts College Medical School, Boston, 1924; died in the Beth Israel Hospital, Boston, Aug. 10, aged 59.

Fischer, Charles ⊕ Philadelphia; Temple University School of Medicine, Philadelphia, 1914; an associate member of the American Medical Association; on the staffs of the Frankford and Episcopal hospitals, and St. Christopher's Hospital for Children; died Aug. 15, aged 75, of coronary occlusion.

George, John Henry, Lexington, Mo.; Kansas City (Mo.) Medical College, 1896; died July 27, aged 88, of senility.

Hecht, Max, Crompond, N. Y.; Long Island College Hospital, Brooklyn, 1914; died May 23, aged 69, of acute coronary thrombosis.

Kaluza, Ernst Karl, Poughkeepsie, N. Y.; Universität Heidelberg Medizinische Fakultät, Baden, Germany, 1922; on the staff of St. Francis Hospital; died June 25, aged 58, of cancer.

Lyon, William Edwin, Des Moines, Iowa; State University of Iowa College of Medicine, Iowa City, 1897; died in the Veterans Administration Hospital, Knoxville, Aug. 3, aged 83, of arteriosclerosis.

Martin, John Franklin, Latimer, Iowa; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1912; for many years mayor and county coroner of Latimer; served on the board of education; member of the staff of the Lutheran Hospital in Hampton, where he died May 3, aged 68, of myocardial infarction.

Peter, Arthur Louis, Alhambra, Calif.; Denver College of Physicians and Surgeons, 1900; served during World War I; died in Huntington Memorial Hospital, Pasadena, Calif., May 17, aged 79, of cerebral thrombosis.

Phelps, Marcus ⊕ Leitchfield, Ky.; University of Louisville Medical Department, 1907; died July 24, aged 74.

Snead, Nash P. ⊕ Cartersville, Va.; Medical College of Virginia, Richmond, 1893; died July 7, aged 81, of embolism and diabetes mellitus.

Stein, Louis Arthur ⊕ Trenton, N. J.; New York Homeopathic Medical College and Flower Hospital, New York City, 1916; on the staff of the William McKinley Hospital, where he died July 18, aged 62, of acute myocardial infarction.

Taylor, Eugene Arthur, Washington, D. C.; University of Virginia Department of Medicine, Charlottesville, 1908; member of the Medical Society of the District of Columbia; for many years on the staff of the Episcopal Eye, Ear, and Throat Hospital; died July 22, aged 71, of acute coronary thrombosis.

Thompson, Clarence George ⊕ Norwichtown, Conn.; New York Homeopathic Medical College and Flower Hospital, New York City, 1919; director of health, Norwich, Preston, and Ledyard; on the staff of the William W. Backus Hospital in Norwich, where he died May 6, aged 66, of cancer.

⊕ Indicates Member of the American Medical Association.

BRAZIL

Brucellosis and Blood Transfusions.—Brucellosis is one of the diseases that may be transmitted by a blood transfusion. Trying to determine the frequency of brucellosis in donors that come to the blood bank at the Hospital das Clinicas of the University of São Paulo, Dr. Carlos da Silva Lacaz and his co-workers performed a serologic survey (*Rev. Assoc. med. brasil.* 1:385 [July] 1955). The results of rapid and slow serum-agglutinations showed the incidence of positive reactions to be very low. The material used in these tests was from donors considered to be perfectly healthy. Using the rapid test of Huddleston and considering a titer of 1:100 significant, 9 positive reactions (1.07%) were obtained in a series of 839 donors. The slow serum agglutination test revealed only two positive reactions, or 0.2% in a titer of 1:160. The readings of serum-agglutinations after centrifugation (Hall and Manion technique) favored the development of false positive reactions. The surface fixation test of Castañeda was negative in all those on whom it was performed in titers higher than 1:40. Although the transmission of brucellosis by the transfusion of blood has been demonstrated in rare cases, the problem is of little practical interest because the disease is not common here. Even so, those who slaughter hogs, workers in refrigerators, butchers, and veterinarians, and all those with suspected brucellosis should be rejected as donors, or rapid serum-agglutination, being easy to do, should be performed on such persons in the blood banks.

Q Fever.—The first clinical case of Q fever in São Paulo is reported by Dr. L. A. Ribeiro do Valle and his co-workers in *Rev. paulista de medicina* (46:447 [June] 1955). In this patient the onset was sudden with headache, malaise, fever, productive cough, and sharp cutting pain on the left side of the chest. Later the patient complained of diarrhea, vomiting, and abdominal pain. On the 10th day of the disease, at the time of the patient's admission to the hospital, an area of slight dulness, fine crepitant rales, and increased tactile fremitus was observed at the base of his left lung. Roentgenograms taken at intervals of several days revealed the findings of an atypical pneumonia. The cause of the disease was established by serologic tests. A significant increase of the complement-fixing antibody titer for Q fever was shown by testing four patient's blood samples collected during different stages of the illness. The complement-fixing antibody titer for the viruses of the psittacosis-lymphogranuloma venereum group was constant in all the blood samples tested. The cold agglutination test was negative as well as the hemagglutination test for influenza A and B.

ENGLAND

Legal Liability in the National Health Service.—Until the introduction of the National Health Service the courts of England and Scotland held that medical practitioners should accept full responsibility in law for the treatment of their patients. Hospital physicians were not considered servants of the hospital in which they worked and were therefore also held legally responsible for their professional actions. Recently, a number of judgments in the courts has shown that this view has been radically changed. Thus, Lord President Cooper in a decision last year expressed the view that "under the new Act and regulations the obligation on the State is to treat the patient and not merely to make arrangements for his treatment by and at the sole responsibility of independent contractors." Lord Justice Denning, giving judgment in a case involving the professional actions of an orthopedist, said: "Whatever may have been the position of a consultant in former times, nowadays, since the National Health Service Act, the term 'consultant' does not denote a particular relationship between a doctor and a hospital. . . . Whether he is called a specialist or consultant makes no difference. He, like the rest of the staff, is merely carrying out the duties of the Minister." The Central Consultants and Specialists Committee of Scotland has circulated a memorandum to all medical practitioners in Scotland. The memorandum states that the National Health Service, whether by intention or not, has established a state hospital service, the medical personnel of which are now state servants in law. This raises important issues, because physicians entered into contract with the new hospital boards established by the act on the assurance that there would be no change in their relationship with the hospital authorities.

The committee states that it does not consider that hospital boards are likely to want to interfere deliberately with clinical discretion but thinks that they may be compelled to lay down rules or procedure for certain categories of medical staff as a safeguard to compensation claims by patients. To support this view the committee quotes a recent case in which legal liability for damages was assigned to the hospital authority because it had allowed a junior medical officer to give a particular anesthetic, with disastrous results. The committee thinks that any form of control on the part of hospital authorities would hamper routine hospital work and the teaching and practice of medicine in the hospitals. Once any form of control or direction is started it is hard to foresee where it would stop. Hospital records are now no longer secret and confidential. Hospital authorities require for legal purposes that medical records be submitted to their own solicitor before passing them on. At present, this incursion of the state has been limited to the sphere of the hospital, but there is no reason why this doctrine of state responsibility should not be extended to the care of patients treated under the National Health Service outside hospitals. If it did, all physicians under contract with the National Health Service would be servants of the state or of local authorities. The committee has invited the Joint Consultants Committee to endeavor to reestablish in law the previous relationship of hospital physicians to the management of hospitals in which they work. This would involve an approach to the Ministry of Health demanding legislative action. As Parliament would have to be satisfied that a change would not jeopardize a patient's legal right to damages when negligence had been proved, governmental agreement to this change would probably be conditional on all hospital medical personnel belonging to a medical protective society, or some other equivalent insurance, as a condition of employment. Although it is recognized that this almost amounts to trade unionism, its acceptance would seem justifiable. The alternative would be the surrender of professional freedom.

Radiographic Use of Edathamil.—The water-soluble chelated compound, lead sodium edathamil, has been shown by Sapeika (*Brit. M. J.* 2:167, 1955) to be of value as a contrast medium for oral and parenteral administration. Edathamil itself is a chelating agent and has been used in the treatment of poisoning by heavy metals such as lead. Results from laboratory studies suggest that lead edathamil might be of practical value for radiographic purposes in man, since dense shadows are obtained with it and its administration by intravenous injection causes no untoward side-effects in the doses likely to be required as a contrast agent. Lead sodium edathamil is soluble in water and being un-ionized does not give the usual reactions of ionized lead; it is therefore nontoxic. Oral administration allows visualization of the esophagus. Administration of 15 cc. of a 50% solution produced renal shadows within three minutes lasting for 30 to 40 minutes. The results are equal to those after use of diodone. A solution of lead sodium edathamil may also be used for visualization of the nasal sinuses, which are filled by displacement in Parkinson's lateral low head position. The lead compound does not appear to irritate the gastrointestinal tract, but, because it produces black stools, due presumably to lead sulfide, this method should be used with caution.

The items in these letters are contributed by regular correspondents in the various foreign countries.

Alkaloids of Rauwolfia.—The alkaloid reserpine, obtained from Rauwolfia serpentina, has been widely used as a hypotensive agent. Unfortunately, a number of patients receiving reserpine complain of side-effects, such as depression, lassitude, drowsiness, rhinorrhea, and nightmares. Another alkaloid, rescinnamine, has recently been isolated from R. serpentina, and its value in hypertensive patients, particularly with regard to side-effects, has been assessed by Smirk and McQueen (*Lancet* **2**:115, 1955). Preliminary observations suggest that an appreciable number of patients under treatment with reserpine who complained of side-effects were relieved of these symptoms by changing to rescinnamine; however, some of these patients suffered from tenseness, anorexia, and abdominal discomfort and preferred to return to reserpine. There was no important difference between the hypotensive effects of the two alkaloids. The central effects of reserpine have been used by Davies and Shepherd for the treatment of anxious and depressed patients (*Lancet* **2**:117, 1955). These patients fared better than did a control group treated with a placebo. Four patients with severe involutional melancholia were unchanged, and the authors believe that reserpine is unlikely to supersede electroshock treatment as the treatment of choice for severe depressive states.

Illicit Drug Traffic.—Illicit drug traffic in Great Britain is very limited, according to a report from the government to the United Nations. Traffic in opium, which is largely confined to the Chinese, is waning, and there is no evidence of synthetic narcotics being unlawfully diverted from their normal channels. Seizures of marihuana markedly increased last year, when 118 kg. (260 lb.) was confiscated. Marihuana is used in Britain mainly by Africans, West Indians, or Asiatics. Known drug addicts in Britain, with a population of about 50 million, number only 317, of whom 148 are men and 169 women. Of the men 66 were physicians, but of the women only 3. Morphine was the drug of addiction in 65% of the cases of known addiction, pethidine (meperidine) in 16%, and heroin in 17%. Only two firms, both in Edinburgh, are licensed to manufacture heroin. In Canada, with a population of 14 million, the number of drug addicts is 3,212, according to an estimate in the recent report to the senate by the Reid Committee on the traffic in narcotic drugs. Half of the 2,364 "criminal addicts" are in Vancouver, the police department of which has been charged with laxity in administration of the drug laws. There is practically no juvenile addiction in Canada, only 26 of the addicts being under 20 years of age.

Detection of Chromosomal Sex.—The skin biopsy test of chromosomal sex is being used with increasing frequency as an aid to differential diagnosis in errors of sex development. The epidermic nuclei in females contain a mass of sex chromatin, but in the epidemic nuclei of males the corresponding mass is inconspicuous. Moore and Barr of the University of Western Ontario, London, have shown that smears from the oral mucosa can be used for the chromosomal determination of sex (*Lancet* **2**:57, 1955). They claim that difficulty is sometimes encountered in obtaining skin sections showing fine nuclear detail. The preparation of mucosal smears has the advantage of simplicity. Both workers independently examined a series of 140 smears without reference to the sex of the subjects from whom they were obtained. The sex was correctly diagnosed in 100% of cases by both examiners. They claim that smear preparations are easier to obtain and interpret than are skin biopsies.

Settlement Out of Court.—Mr. Justice Pilcher, giving judgment on July 1 in an action against a hospital management committee, suggested that in certain cases it might be advisable for committees to make a small payment to plaintiffs without any admission of liability rather than having experienced physicians "dragged through the courts." On the previous day he had warned against actions taken against individual physicians or hospital management committees for negligence in cases where damages were likely to be small.

Malaria.—Although rife in the 17th century, malaria has disappeared in Great Britain. Malaria-carrying mosquitoes have recently appeared in Gosport, near Portsmouth, and cases of malaria have been reported in the district. Navy, Army, and Air Force medical departments are joining the local health officers to stamp out the threat. Mosquitoes tend to breed heavily in the area because of the prevalence of stagnant or slow-moving waters. Householders have also been warned of the danger and told how to use sprays to keep their numbers down.

SWITZERLAND

Cancer of the Respiratory System.—Dr. M. Pascua, Director-Consultant on Health Statistics, World Health Organization (*Bull. World Health Organ.* **12**:687, 1955), reviewed the mortality statistics for cancer of the respiratory system for the years 1949 to 1952 in 10 European and 5 non-European countries. The levels of recorded mortality from malignant tumors of the respiratory system, for either sex, differ greatly between countries, and the death rate from these causes has risen markedly, mainly in men, in those countries in the course of the four years under study. The author concludes that the divergency between countries may be caused, apart from different age and sex distribution of the populations, by variations in medical facilities, reliability of cause-of-death certification, and perhaps the proportion of population living in urban and rural areas. The rate of increase was much sharper in some countries for men. Women showed in some of the countries no significant increase or no increase at all. This study, even with its limited scope, would not favor the idea that improvements in diagnosis and in reporting causes of death (although these may be factors) is the chief cause of the increase. Also, the drop in mortality from tuberculosis and from some other respiratory diseases may have facilitated the diagnosis of cancer otherwise masked by the symptoms of such diseases. Some real increase in bronchopulmonary cancer has occurred in the last few years, but the reasons for this are not clear. The aging of the male population cannot be made primarily responsible for the increase observed. While this rise has mainly occurred in tumors of the trachea, bronchus, and lung, a similar inference for women is not apparent or clearly substantiated. Mortality from cancer of such accessible sites as the nasal cavities, middle ear, sinuses, and larynx has not increased during this period. The increased mortality from respiratory cancers has generally been concentrated in the age span 40 to 85 years.

International College of Allergists.—At the second meeting of the International College of Allergists in Basel in July, Wolff of New York distinguished three phases in the migraine attack: the vasoconstrictor, the vasodilator, and the edematous. The aura, often a scotoma, is attributed by the author to vasoconstriction of the retina or calcarine cortex. He stated that vasoconstriction can be seen and photographed in the retina, that during this phase the vessels of the bulbar conjunctiva are narrowed and abnormally sensitive to arterenol that is applied locally, and that the scotoma can be relieved temporarily by vasodilator drugs such as amyl nitrite. Vallery-Radot of Paris stated that, during the phase of headache, ergotamine tartrate, by subcutaneous or intramuscular injection, was the most efficacious agent. In doses of 1 mg. it can also be given orally in combination with 100 mg. of caffeine or, if vomiting is troublesome, as a rectal suppository of 2 mg. of ergotamine and 100 mg. of caffeine. Krayenbuhl of Zurich thinks that to prevent attacks dihydroergotamine is the most efficacious drug in patients showing vasomotor instability, while in attacks possibly related to epilepsy, a combination of Mesantoin and caffeine is best.

Storck, Hoigne, and Grossman of Zurich presented a new serologic method for identifying allergens. They had shown previously that an allergen added to a sensitized serum would cause conglomeration of the platelets. They now showed, using a sensitive nephelometer, that adding an allergen to a sensitized serum causes turbidity at certain dilutions of the allergen. They also demonstrated that the capacity of serum to react with the allergen is due to the presence in it of a specific factor that reacts only with the allergen and that dialyzes through cellophane and a nondialyzable, nonspecific factor that is present in the serum of guinea pigs, cows, and horses but is absent from that of rats and rabbits.

Familial Bilateral Nephropathy.—Although the importance of heredity in persons with polycystic kidney, malformations of the kidney pelvis, renal dystopia, and changes in renal form and volume is recognized, the role of this factor has not been pointed out in bilateral medical nephropathy. M. Poli (*Helvet. med. acta* **22**:109, 1955) has studied one family with nephropathy for several years. Of 92 members, 28 living during the period of observation were examined. Albuminuria was a constant finding in 16 (56.9%) and hematuria in 17 (60.8%). Eight surely, and probably 10, had died of this disease. Autopsy of a 20-year-old patient who died of uremia showed that the disease was of a highly atypical nature. It differs from malignant nephrosclerosis in that the vascular lesions are milder and from albuminuric and membranous nephritis in that the basement membranes are not so thick, not to mention the wholly different clinical findings. Anatomically, bilateral medical nephropathy most closely resembles subacute ascending pyelonephritis, except for the lack of pyuria. Thus this family were all affected with a disease of relatively uniform clinical development, always commoner among the men and characterized by the following symptoms: (1) early appearance of slight albuminuria, (2) progressive development of urinopathy with hematuria as the leading symptom, (3) late appearance of hypertension correlating with the severity of the renal lesion, (4) late appearance of nitrogen retention, hyposthenuria, and glomerular filtration insufficiency, and (5) late death from renal insufficiency and uremia.

Pulmonary Staphylococcia.—Among the manifestations of superinfection observed during antibiotic therapy, the mycoses (notably those with Candida albicans) and the staphylococcias are well known. The best known complication caused by Micrococcus (Staphylococcus) pyogenes var. aureus is pseudomembranous enterocolitis. Complications occurring in the lungs have had less attention, despite reports by Jackson and co-workers on the changes in sputum flora in patients treated with the tetracyclines. At a meeting of the Swiss Society of Internal Medicine in Geneva in May, Rentchnick and Wolhers reported a case of this enterocolitis after oxytetracycline therapy. A later development was pulmonary localization producing the findings of a tuberculous cavity. In view of the patient's poor general state, wasting, and fever, this diagnosis was possible but was finally excluded when no tubercle bacilli were found in the sputum and M. pyogenes aureus were found. Intensive erythromycin therapy caused rapid clinical improvement with return of appetite and weight gain. The cavity, however, persisted for eight months. It was no doubt a residual cyst. This case shows that micrococcic lesions have entered on a new era as the result of antibiotic therapy. Visceral and osseous localizations are possible, calling for new skills in diagnosis and treatment. Roentgenograms of the chest must be made in patients with enterocolitis from micrococci.

Rare Form of Hyperthyreosis.—Up to 1938 there was no literature on the repercussions of the acromegalothyroid complex on the gross and microscopic morphology of the skeleton. At that time, independently of one another, Troell of Sweden and Junet of Geneva studied this matter. The Troell-Junet syndrome consists of acromegaly, toxic goiter (usually nodular), diabetes mellitus, and hyperostosis of the cranial vault. So far it has been reported only in women. It seems that a hypophysial adenoma uncomplicated by goiter is incapable of producing the cranial thickening. Hyperthyroidism without acromegaly has shown no other hyperostotic picture than the highly localized one of nebula frontalis. The coexistence of these two affections is common to all the cases reported by Troell, Moore, Davis, and Junet. It is to be expected that the syndrome will appear more frequently in a country like Switzerland, where goiter is endemic, than in countries where it is rare. Microscopic examination of bone tissue shows intense osteogenic activity in the periosteum and endosteum. In a patient recently described by Junet, there was generalized spongy transformation of the skeleton. This finding allows for differentiating between the anabolic effect of the hypophysial growth hormone and a catabolic effect presumably resulting from hypersecretion on the part of the proliferating goiter.

Cortisone for Leukemia.—Present therapy of acute leukemia combines blood transfusions with 200 to 300 mg. doses of cortisone and an antimitotic drug (aminopterine or 6-mercaptopurine). In certain fulminating cases with swift deglobulization and hemorrhage, a drastic increase in cortisone dosage was tried recently. One gram was given, then two, and then up to five. H. Dubois-Ferrière treated a 19-year-old man with acute leukemia with 3 gm. of cortisone a day for eight days consecutively. In 10 days, complete clinical, hematological, and medullary remission was obtained. There is no satisfactory explanation of how this remission could occur unaccompanied by the secondary effects caused by doses 10 to 20 times smaller. There was no fluid retention in this patient, nor was there any disorder of his electrolyte metabolism. Only slight rounding of the face appeared. The long range value of this procedure is not known, but it is a promising treatment for emergencies in acute leukemia (*Méd. & hyg.* **13**:318, 1955).

TURKEY

Cerebral Hemangioma.—In *Tib Dünyasi (Medical World*, vol. 25, no. 4) Polvan and Kerimoglu described a 31-year-old man who complained of intermittent muscular tremors in the left arm and syncope. These were first noted on the day his mother died. The syncope had lasted half an hour and was followed by numbness in his left arm. Since then he had had these attacks four or five times a week when he was worried. Vertigo, headache, and tremor in the arm preceded the attacks. On the day after admission to the hospital he had an epileptic seizure. The onset was marked by tremor in the left hand and arm and passed from the left to the right side of the face; after the epileptic cry he had severe clonicotonic convulsions and loss of consciousness. There was incontinence during the crisis, and the patient did not bite his tongue. He had a positive bilateral Babinski sign. Confused consciousness returned after 20 minutes. On admission the muscle tonus of his left hand was 80% below that of his right. After an attack he had pain, numbness, and tingling in his left arm. Pressure on his fourth cervical vertebra elicited pain and a feeling of warmth in his left arm and hyperesthesia, astereognosis, and dermalaxia in his left hand. He had diapasonic anesthesia and defective orientation. Percussion of the cranium elicited a right parieto-occipital dulness. The patient had difficulty moving his head and he had dysdiadochokinesia of the left hand. His IQ was 50 (Binet-Terman test). The spinal fluid pressure, when seated, was 45 mm. H_2O and when recumbent, 22. Roentgenograms revealed a mass the size of a small orange in the right posterior parieto-occipital region. Several formations pointing in different directions and of different densities were seen in its interior. The right side of the face was slightly less developed than the left. Electroencephalography recorded 20 to 75 μv, 8 to 12 alpha waves, 14 to 20 cps frequency, and 14 to 30 cps μv beta waves. A diagnosis of cerebral hemangioma was made. The patient refused operation.

Quinacrine for Teniasis.—In *Dirim* (vol. 30, no. 7) Özgen and Tartaroglu described how a patient expelled five Taenia saginata after treatment with quinacrine. This 38-year-old woman had been advised to include plenty of meat in her diet because of a history of pulmonary tuberculosis. She was admitted because of hypertension of three years' duration. She also mentioned that she expelled tapeworm segments in her stools. On an empty stomach and by means of a duodenal catheter, bile was removed and 0.9 gm. of quinacrine, dissolved in 150 cc. of distilled water, was directly introduced into the small intestines. After half an hour this was followed by the introduction, again through the catheter, of 30 gm. of magnesium sulfate. Half an hour later the patient expelled five scolexes of T. saginata. The worms measured 2 to 3 m. The authors have used this therapy many times and only once encountered two scolexes in one patient. Introduction of quinacrine through the catheter proved effective in all cases and no toxic reactions were observed.

CORRESPONDENCE

PERCUTANEOUS SPLENOPORTOGRAPHY

To the Editor:—In THE JOURNAL of June 11, 1955, page 478, Dr. T. B. Reynolds, Dr. W. Mikkelsen, and Dr. A. G. Redeker in an article, "Splenic Hemorrhage Following Percutaneous Splenoportography," report their experience on splenoportography employed in three cases. After the percutaneous injection of the contrast medium into the spleen, they have observed in the first case a significant subcapsular hematoma; in the second injection, done during surgery, a brisk bleeding controlled by pressure; and, in the third injection, a significant splenic hemorrhage (1,500 cc. of liquid blood in the peritoneal cavity and a large hematoma distending the splenic capsule) that required a splenectomy. They conclude that the procedure is more hazardous than the reports of the literature indicate and because of the splenic hemorrhage facilities for splenectomy must be available.

I was astonished in reading this article. I have done almost 150 splenoportographic examinations in both normal cases and many different pathological conditions of the spleen, pancreas, and liver. Part of my experience has been published (Catalano, D., and Giardiello, A.: Splenic Venography, *Am. J. Roentgenol.* 73:971-973 [June] 1955; Catalano, D., Giardiello, A., and Ruggiero, A.: Hepatography After Percutaneous Lieno-Portal Venography, *Acta radiol.* 43:285-288 [April] 1955). We have never had a significant complication. In some of our cases, in which surgical procedure was performed after the roentgenological examination, we could find a laceration of the splenic parenchyma at the site of the injection and in very few of them a small subcapsular hematoma or a few cubic centimeters of blood in the peritoneal cavity. Our experience is confirmed by others, including Abeatici and Campi, Leger (more than 200 splenoportographies), Bourgeon and co-worker, Fuld and Irwin, Caroli and Porcher, Sotgiu and co-workers, and Leroux and de Scoville.

Although we must be grateful to Dr. Reynolds and co-workers for their report that will make us more cautious in performing this procedure, we think because of our experience that splenoportography is without serious complications. The value of the examination is very well known and is unquestionable. Of course, like other vascular contrast studies, it must be performed only in selected patients where useful information may be obtained. Another question that must be taken into consideration is the risk of injection of contrast medium into the peritoneal cavity, referred to by Dr. L. G. Rigler and Dr. P. C. Olfelt (Abdominal Aortography for the Roentgen Demonstration of the Liver and Spleen, *Am. J. Roentgenol.* 72:586-596 [Oct.] 1954). This happened to us in some cases without any danger. With a proper technique the peritoneal injection can be avoided, but if it occurs it is without danger.

DINO CATALANO, M.D., Roentgenologist
Surgical Clinic of the University
Naples, Italy.

APPRAISAL OF NEW DRUGS

To the Editor:—In his letter to the Editor, in THE JOURNAL, Aug. 27, page 1547, Dr. Robert C. Batterman is not challenging Dr. Russek but is instead questioning the validity of the scientific method as applied to medicine. The use of controlled, unbiased observations is fundamental in the approach of science and cannot be summarily dismissed by the as yet unpublished observations of Dr. Batterman. If his double-blind controlled studies failed to reveal any significant therapeutic value in any one or more presumably potent drugs, as compared to placebo, it surely indicates the need for further scrutiny of the true value of these drugs under experimental and clinical conditions. Instead of being shocked into concluding that controlled experimentation is valueless, it would seem more rational for Dr. Batterman to have investigated the circumstances that produced double-blind results at variance with accepted clinical experience.

Were his subjects well chosen in terms of symptomatology? Were the circumstances of his experiments arranged adequately to simulate those of the usual patient-physician relationship? Did his experiments provide for a group of patients whose dosage schedules could be adjusted to the responses of the individual subject, while still maintaining double-blind conditions?

In studies of a similar nature we have been performing at Jackson Memorial Hospital since 1953 (data in preparation for publication), we have found that we could simulate the usual circumstances of the patient-physician relationship in the use of therapeutic agents by dividing the subjects of our double-blind study into three groups. At the time of each of a series of patient-interviews, the physician recorded his observations of clinical change, and, in accord with this evaluation, he was provided with the opportunity to advise changes in the frequency and magnitude of dosage of the therapeutic agent in question, which was being administered by injection. His specific recommendations were only carried out in subjects who happened to fall into the third or experimental group. In the first group each patient received injections of inert placebo, and in the second group they received doses that were constant in frequency and magnitude.

If this type of an experiment, performed under strict double-blind conditions, should fail to demonstrate the superiority of a presumably potent drug over inert placebo, any insistence that this drug must still have value can only be classified as cultism and a denial of the scientific method as applied to medicine.

BERNARD D. ROSS, M.D., PH.D.

Miami, Fla.

OUTBREAK OF HERPANGINA IN TOKYO

To the Editor:—An outbreak of herpangina occurred in Tokyo from April of this year; over 60 patients have been observed. Many of the cases occurred in several dormitories scattered in Tokyo, which include from about 40 to over 100 households, whereas about 15 cases are sporadic. The clinical picture, throat lesions, clinical course, age distribution, and other features correspond closely with those described in the United States by Zahorsky, Levine, and others; Huebner and others; Parrot and others; and Kravis and others. Clinical and etiological studies are now in progress. Attempts to isolate the causal agent in suckling mice were carried out, and almost all fecal specimens from patients tested were found to contain Coxsackie virus; each of the suckling mice inoculated with fecal specimens from patients developed the typical flaccid paralysis characteristic of Coxsackie virus infection. Those strains isolated seem to belong to group A of Coxsackie virus from the clinical symptoms manifested in suckling mice and the histological picture of infected mice (selectively in muscle). Typing of the isolated viruses has now been carried out by neutralization tests with prototype of a known type of Coxsackie virus. As yet the typing experiments are not finished; one strain, Omura, is identical with Fleetwood strain (A2), and the other one, Mitsuhashi, is identical with Kudo strain, which was recovered from a patient with paralysis in 1952 in Tokyo and is serologically not related to A1, A2, A3, and A4 but belongs to group A. Isolation tests from the healthy contacts and the demonstration of antibodies in paired patients' serums are now in progress.

INTERNAL MEDICINE

Treatment of Hypertension with Reserpine (Serpasil) Alone and in Combination with Hydralazine (Apresoline). L. J. Stuppy and J. N. Tober. Angiology 6:253-259 (June) 1955 [Baltimore].

Reserpine (Serpasil), a pure crystalline alkaloid derived from the roots of Rauwolfia serpentina, was used in the treatment of 83 patients with hypertension. The group included 15 men and 68 women, and the ages varied from 34 to 80 years. All degrees of essential hypertension were represented. Two patients had previously undergone sympathectomy, and two had been treated with radioactive iodine for thyroid disease. Complications such as myocardial infarction, hypertensive encephalopathy, cerebral thrombosis, and renal insufficiency existed in some of the patients. Five of the patients also had asthmatic bronchitis, and two had aortic insufficiency with severe systolic hypertension. All were outpatients. The dosage of reserpine ranged from 0.25 to 2 mg. per day. Results appeared to be equally good whether the total daily dose was given at bedtime or in divided doses during the day. Since sufficient data had been collected on all patients prior to treatment, a placebo control series was not considered necessary. Reserpine alone did not produce adequate reduction in blood pressure in 15 of the patients. These patients were given hydralazine (Apresoline) hydrochloride in addition to the reserpine, the daily dose of reserpine ranging from 0.5 to 2 mg. and that of hydralazine hydrochloride from 50 to 800 mg. Reserpine counteracted the tendency of hydralazine hydrochloride to produce tachycardia, and the two drugs acted synergistically in reducing blood pressures. Patients received treatment for a maximum period of 12 months, and the reduction in blood pressure was satisfactory. In patients in whom tachycardia accompanied hypertension, reserpine reduced the pulse rate. Untoward reactions required discontinuation of the drug in only seven patients. Symptoms like drowsiness, looseness of stools, nasal stuffiness, or vertigo were usually so mild that the patients could continue their medication. Studies on the peripheral blood indicated no changes in the hemopoietic system.

Widened Prophylaxis of Thromboembolism with Anticoagulant Drugs in Internal Medicine. E. Scharpff and R. Seitz. Medizinische, no. 27/28, pp. 976-979 (July 9) 1955 (In German) [Stuttgart, Germany].

Between 1951 and 1954, 250 patients with venous thrombosis were admitted to the medical department of a general hospital in Hamburg, Germany, and were treated with anticoagulant drugs for an average of 25 days. Recurrences occurred in six patients soon after discontinuation of the anticoagulant therapy, but there were no recurrences in the course of the therapy. Observations on the authors' patients and reports by other workers culled from world literature suggest that involvement of the other extremity by venous thrombosis can be checked by anticoagulant therapy. Dreaded pulmonary embolism can be prevented, temperature can be restored to normal, and bedfastness can be reduced. A psychological advantage of anticoagulant therapy is the possibility of removing from the patient the fear of pulmonary embolism, a complication that up to now was known to be fatal. With the exception of pulmonary infarction with an initially fatal course, it can be considered as proved that, as a result of anticoagulant therapy, pulmonary embolism is beginning to lose its horror; its mortality has been reduced to an unexpected degree, and, in addition to the prevention of recurrences, the basic thrombotic process can be controlled. The incidence of pulmonary embolism in patients with internal diseases is higher than in surgical patients, and its diagnosis is often more difficult in patients of the first type. Widening of the indications for anticoagulant therapy of pulmonary embolism depends on an extended diagnosis. The deep-rooted belief that pulmonary embolism is an acute condition and that its criterion is sudden death is erroneous. A silent or subacute chronic course may occur in about 82% of the fatal cases. Subicterus; serous, but bilirubin-positive, pleural exudate; tachycardia refractory to digitalis; nausea; short fainting fits; shortness of breath; and slight cough may be observed frequently. Electrocardiographic changes with the phenomenon of acute cor pulmonale in the peripheral leads and acute and subacute cor pulmonale in the thoracic wall leads may be an aid to diagnosis. Certain cardiac patients with "thromboembolic constellations" may require early institution of antithrombotic measures. These constellations may be permanent or only temporary. Removal of edema by the administration of mersalyl may produce an increased viscosity of the blood and slowing of the blood stream, and decreased hepatic congestion may result in an increased tendency to thrombosis caused by an increase in the coagulation-enhancing factors. Early anticoagulant therapy directed at preventing irreversible changes of the heart muscle is indicated in disorders of the coronary vessels for which the term preinfarction (threatened infarction, acute angina pectoris) has been coined. This applies also to other diseases of the heart with a similar severe thromboembolic risk. Carefully planned institution of anticoagulant therapy instead of "treatment with anticoagulants in every case" made it possible to reduce the mortality of cardiac infarction from 41% in 1951-1952 to 16.9% in 1953-1954. Extended use of anticoagulants such as 3-(1-phenylpropyl) hydroxycoumarin (Marcoumar), ethyl biscoumacetate (Tromexan), heparin, and isonicotinic acid-3-sulfonic acid neodymium in 0.7% sodium chloride solution (Thrombodym) seems to be justified by the satisfactory results obtained with these drugs in patients with venous thrombosis, pulmonary embolism, and coronary thrombosis.

Cancer of the Respiratory Tract: Recent Trends in Mortality. E. A. Lew. *J. Internat. Coll. Surgeons* **24**:12-27 (July) 1955 [Chicago].

Statistical data, illustrated with charts and tables, on the death rates from cancer of the respiratory tract in the general population of the United States and among industrial and ordinary policyholders of the Metropolitan Life Insurance Company indicate that during the past 25 years the white male mortality from cancer of the respiratory tract, adjusted for changes in age distribution, increased five times. An increase of this magnitude and rapidity appears greater than can be accounted for solely by better diagnosis, case finding, and reporting, especially as no other site of cancer has shown so large a proportionate increase. The increase is continuing despite the fact that the disease is now more generally recognized. Among white females, mortality from cancer of the respiratory tract, adjusted for changes in age distribution, has only doubled in the past 25 years. If all this increase were due to better detection and reporting, it would be still smaller than the increase in white male mortality. This suggests that a considerable part of the increase in white male mortality from this disease cannot be accounted for in this manner, since it is difficult to see why physicians should be able to diagnose cancer of the respiratory tract more readily in one sex than in the other. The magnitude of the increase in death rates of cancer of the respiratory tract over the past 25 years varied by age, being smallest at ages

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1946 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

under 45, and greatest at the more advanced ages. The markedly higher death rates from cancer of the respiratory tract among white male industrial policyholders as compared with those for white males in the general population cannot be explained in terms of better diagnostic facilities in urban areas, since white female industrial policyholders residing in the same area showed death rates from cancer of the respiratory tract substantially the same as those for white females in the general population. The reasons for the higher death rates of white male industrial policyholders must rather be sought in some environmental factors. The lower death rates from cancer of the respiratory tract among white male ordinary policyholders, who presumably have access to even better diagnostic facilities than industrial policyholders or white males in the general population, also suggest factors related to environment, occupation, and social class. In this connection, it may be noted that several life insurance studies have indicated somewhat higher than average mortality from cancer of the respiratory tract in such numerically important occupations as painters, roofers and slaters, carpenters and cabinet makers, coppersmiths and tinsmiths, and electricians. The geographical variations in death rates from cancer of the respiratory tract in the general population likewise indicate that some environmental factors may be contributing to produce the higher death rates observed in the most urbanized and industrial states. The high age-adjusted death rates in states such as Louisiana, Florida, and Nevada also appear to require explanation in terms of special factors. There is reasonably convincing statistical evidence that a number of different factors may be implicated in the rise in the incidence of cancer of the respiratory tract. Adequate data are not available to show how much of the rise can be attributed to the effect of specific factors.

Indications and Results of Lung Needle Biopsy. M. Fazio, E. Minetto and R. Garbagni. Minerva med. **46**:1559-1567 (May 30) 1955 (In Italian) [Turin, Italy].

During the last five years the authors examined 455 patients with various conditions of the lungs. In only nine patients did they find it necessary to resort to needle biopsy to establish the diagnosis. These patients' roentgenograms had shown round shadows of the lung near the thoracic wall. Lung biopsy is particularly indicated for this topographic location. The procedure should never be used when the shadow is near the hilus or in areas in which branches of the pulmonary vessels may be injured while it is performed. Nor should it be used in patients with high fever, heart disease associated with stasis of the pulmonary circulation, cardiovascular collapse, recent hemoptysis, the coexistence of bronchopneumonic foci, or the presence of progressive tuberculous lesions or in patients in whom an aneurysm or an Echinococcus cyst is suspected. Eleven lung biopsies were performed on the nine patients. It was possible to establish a diagnosis of primary malignant neoplasm in five, bronchial cyst in one, sequelae of pleurisy in two, and pleural mesothelioma in one. A mild subcutaneous emphysema in the area surrounding the site of the puncture was observed in one patient, a transitory onset of capillary bleeding in two, and a moderate hemorrhage followed immediately by the excretion of purulent matter (evidence that the bronchial drainage had been restored) in one. The authors conclude that lung needle biopsy can be a decisive diagnostic means in peripheral lesions of the lung and the technique of choice in cases in which a diagnosis cannot be reached by the standard means.

Results of Scalene Node Biopsy in Patients with Pulmonary Calcifications. J. E. Johnson Jr. Am. Rev. Tuberc. **72**:91-97 (July) 1955 [New York].

The author performed scalene lymph node biopsy in 50 consecutive male Air Force recruits with pulmonary calcification. The men were also subjected to clinical study and were skin tested with histoplasmin, coccidioidin solution, and purified protein derivative. The place of residence of the recruits and the results of the skin tests indicated that the majority of these calcifications were probably of histoplasmic origin. In five recruits the scalene node biopsy revealed pathological material. From one scalene node a virulent culture of Histoplasma capsulatum was obtained. Two nodes were histologically consistent with sarcoidosis; these nodes were not cultured for histoplasmin. Two nodes showed a nonspecific inflammatory change. Because of the difficulty in prognostic interpretation of results in the relatively small number of cases with abnormal scalene node findings, the author feels that the procedure is not economical for routine evaluation of patients with pulmonary calcifications. It should prove to be a useful procedure when clinically indicated for diagnostic purposes and for further study of histoplasmic infection.

SURGERY

Case of Acromegaly Associated with Thyrotoxicosis: Review of Literature. J. P. Heaney, C. L. James, C. L. Spurr and M. E. De Bakey. A. M. A. Arch. Surg. **71**:279-287 (Aug.) 1955 [Chicago].

In acromegaly, thyromegaly and thyrotoxicosis often coexist to complicate the therapeutic problems as well as the prognosis of the pituitary disorder. Moreover, the clinical picture of disease of these two endocrine organs may be additionally confused by the simultaneous dysfunction of other endocrine glands, notably the pancreatic islet cells. The 29-year-old man whose case is presented was hospitalized in September, 1949. He had first noted enlargement of chest, hands, and feet in 1943. During 1948 headaches, polydipsia, polyphagia, and polyuria developed. In February, 1949, he became sexually impotent. At about the same time he noticed enlargement of the neck, hoarseness, mild dysphagia, and hacking cough. For six months prior to admission he had been troubled by increased intolerance to heat, with excessive sweating, muscular weakness, fatigue, cardiac palpitation, and dyspnea on exertion. He had lost a moderate amount of weight in spite of an increase in appetite. Physical examination revealed the prognathism and enlargement of the hands and feet characteristic of acromegaly. The supraorbital ridge was prominent, and exophthalmos was moderately advanced. The tongue was large. The thyroid was considerably enlarged and nodular. Roentgen-ray therapy to the pituitary was recommended in September, 1949; however, it was decided that the thyrotoxicosis should be treated by a thyroid-blocking agent, and administration of propylthiouracil was begun. The dosage was approximately 200 mg. three times daily. Because of lack of response to the thyroid-blocking agent and because of development of severe exfoliative dermatitis, propylthiouracil therapy was discontinued on Nov. 26, 1949. Administration of strong iodine (Lugol's) solution and roentgen-ray therapy to the pituitary were started at once. The patient's condition was so grave that it was no longer possible to rely upon a single agent. Roentgen-ray therapy was given through three 5 cm. ports, one anterior and two temporal; 2800 r were delivered to each. The patient's condition improved. On Jan. 3, 1950, total thyroidectomy was done. The postoperative course was uneventful. In March, 1954, the patient's condition was still satisfactory. Literature reports support the contention that the hypermetabolism of acromegaly is due not only to possible associated thyrotoxicosis but also to some direct action of the pituitary gland. Various forms of treatment have been used for both the acromegaly and complicating hypermetabolism. In the absence of hazardous pressure symptoms from either the pituitary tumor or the thyromegaly, initial therapy should consist in external irradiation of the pituitary gland. If adequate radiation therapy fails to control the hypermetabolism, total thyroidectomy should be performed after the patient has been prepared with strong iodine solution. Acromegalic patients with laryngomegaly are more likely to need temporary tracheotomy after thyroidectomy than other patients, even in the absence of recurrent laryngeal nerve injury. The presumed fear of progression of acromegaly after thyroidectomy seems unjustified.

Results of Thoracolumbar Sympathectomy for Essential Hypertension: Three-to-Seven-Year Follow-Up of One Hundred Patients. H. A. Zintel, J. A. Mackie, A. M. Sellers and others. A. M. A. Arch. Surg. **71**:215-222 (Aug.) 1955 [Chicago].

Seven years ago the authors subjected a number of patients to thoracolumbar sympathectomy and followed these patients closely. At the present time 100 patients have been followed for from three to seven years, with an average postoperative follow-up of five years and two months. Surgical treatment was employed for the following reasons: (1) because the patients had severe forms of the disease, generally a diastolic blood pressure of more than 120 mm. Hg; (2) because they did not do well on other types of therapy and principally because they showed evidence of progressive vascular damage; and (3) because their status indicated a very poor prognosis. Surgical treatment was refused to patients with azotemia, to those who had had a coronary occlusion or a cerebrovascular accident within three months, and to those who had permanent severe cerebral damage, although 19 of the patients operated on had had strokes and there were 9 others who had had previous cerebral vascular accidents with residual neurological signs at the time of operation. The preoperative status of the patients is recorded in regard to symptoms, retinopathy, cardiac abnormalities, phenolsulfonphthalein excretion, serum blood urea nitrogen levels, average normal urea clearances, and Smithwick grouping. The operative procedure used was slightly more extensive than the procedure described by Smithwick. It is not possible to state whether the better survival rates observed were due to the more extensive resection. The data reported here would indicate that group 4 and 5 patients as well as group 1, 2, and 3 patients are suitable candidates for operation, because the average five year survival rate of group 4 and 5 patients is more than 50%. This is considerably better than the five year survival rate for group 4 and 5 patients not treated surgically. Two operative deaths resulted in the 100 patients. Eighty-five per cent of the living patients consider themselves improved.

Extension of Radical Mastectomy to Include the Internal Mammary Lymph Node Chain. J. A. Urban. West. J. Surg. 63:463-469 (July) 1955 [Portland, Ore.].

The classical radical mastectomy has so far produced the best therapeutic results in cancer of the breast. The author feels that further improvement will be obtained primarily through earlier diagnosis and through early, more radical surgical treatment. The most logical extension of the radical mastectomy procedure is the inclusion of the en bloc resection of the internal mammary node chain, since breast cancer drains primarily into two main lymph node systems, the axillary and the internal mammary chain. A practical technique has been worked out, in which the internal mammary chain is removed en bloc in continuity with the breast, pectoralis muscles, and axillary contents. Closure and stabilization of the defect in the chest wall has been accomplished with a free fascia lata graft. So far this operation has been carried out on 160 patients with only one postoperative death. The internal mammary node chain was found to contain cancer tissue in 36% of the first 150 patients, while the axillary nodes were found to contain cancer tissue in 54% of the patients. Thirteen per cent of the women in whom the axillary nodes were free from cancer were found to have cancer tissue in the median chain of nodes. The author operated chiefly on patients with inner quadrant breast lesions, since these show a greater incidence of metastases in the internal chain of lymph nodes. Early results of this operation have been encouraging. The author feels that this operation is especially indicated for stage 1 and early stage 2 lesions, particularly when the breast lesion presents below the nipple or in the medial portion of the breast. He does not believe that this more radical procedure can save the patient with advanced breast cancer.

Results of Surgical Treatment of Lung Cancer. M. Bérard, E. C. Saubier and G. Maret. Lyon chir. 50:534-546 (July) 1955 (In French) [Paris, France].

A statistical study was made of 131 patients with pulmonary cancer treated surgically between January, 1948, and November, 1954. Among the first 53 excisions there was a mortality of 15 (28%), while among the last 55 (performed after 1951) there were only 4 deaths (7%). The remaining 23 patients had exploratory thoracotomies only. The basic difference between the first and second operative series lies in the anesthetic technique used. In the first series, deep anesthesia under controlled respiration was the cause of several deaths during operation or immediately afterward. In the later series, the light anesthesia used caused no complications, and all the deaths can be attributed to operative accidents. Despite the high proportion of early recurrences of small-cell carcinoma, some significant results were obtained, namely, three five year survivals, one four year survival, and four three year survivals. Of the 108 excisions, 95 were pneumonectomies and 13 were lobectomies. It is logical to perform a lobectomy in any patient in whom the anatomic features of his disease permit and especially in elderly patients, more particularly if they are operated on the right side. The inoperability of a cancer with opened thorax cannot be judged until after the pericardium has been opened. Following this rule, the authors obtained surgically good results in more than 80% of their last 50 patients who underwent thoracotomy. When total excision has been decided on, the so-called expanded pneumonectomy should be used.

Extrapleural Pneumothorax and Thoracoplasty in Extreme and in Hyperchronic Cases. A. Rabino, F. Sacco and A. Gaida. Minerva med. 46:1660-1663 (June 6) 1955 (In Italian) [Turin, Italy].

A comparison between interventions of extrapleural pneumothorax and thoracoplasty performed in patients with severe cases of tuberculosis before and after 1948 indicated that 30% of these operations were performed before as compared with 55% after that year. The antibiotics have made it possible to operate on patients with severe lesions who could not have been subjected to surgery in the preantibiotic era. Of 242 patients operated on by the authors during the last few years, 128 were severe or highly chronic cases. Of these, 46 were improved; the results were good in 58 and poor in 20; and 4 patients died. The rate of complete recoveries was 45% in the advanced cases as compared with 87% in the other cases in which these interventions were performed. Extrapleural pneumothorax gave good results in 64% of the cases whereas with thoracoplasty the results were good in 42% only. A greater number of residual cavities is observed after thoracoplasty. The authors conclude that extrapleural pneumothorax should be preferred to thoracoplasty when operating on patients with severe cases of tuberculosis because it is more useful and less dangerous.

Chondromatous Hamartoma and Pure Chondroma of Lung. I. Novi. Arch. ital. chir. 79:315-336 (No. 4) 1955 (In Italian) [Bologna, Italy].

Three cases of benign cartilaginous formations in the lung are reported. The mass in two patients was endobronchial and was removed by lobectomy. The microscopic structure was typical of a chondromatous hamartoma. The third case was discovered at autopsy in the victim of a traffic accident. The mass was found within the lung parenchyma, and histological studies revealed that the structure consisted exclusively of cartilaginous tissue. The author considered this a pure chondroma of the lung, which he defines as a true neoplasm arising from the preexisting bronchial cartilages. Less than 200 cases of chondromatous formations in the lung have been reported in the world literature. The condition, which is more common in male patients, is found mostly in the lower lobes, often in the central areas, and less frequently in the peripheral areas in close contact with the pleura. In rare instances, these formations, which are generally of a hard, stony, and rubbery consistency, are in direct relationship with a bronchus. Sometimes they develop within a bronchus and are seen in the lumen in the form of a polyp. The microscopic structure is composed of mesodermal, epithelial, and, sometimes, fat elements in a well-defined and uniform architectural pattern. In some instances, only cartilaginous tissue—normal or metaplastic—is present (pure chondroma). Symptoms, except for instances in which the mass is extremely large or in direct relationship with a bronchus, are of little diagnostic help. In instances in which the mass lies within the lung parenchyma, differential diagnosis should be made from hydatid cysts and tuberculomas. The intrapulmonary forms can often be enucleated quite easily; when they cannot, lobectomy and, sometimes, pneumonectomy give excellent results. The clinical roentgenologic, and bronchoscopic findings of endobronchial chondromatous formations are similar to those of bronchial adenoma. These masses can be removed by endoscopy or [illegible] chotomy only if the diagnosis has been confirmed by biopsy; otherwise pulmonary resection is required. A definite preoperative diagnosis of these formations is impossible most of the time.

NEUROLOGY & PSYCHIATRY

Hereditary Combined Neurinomas and Meningiomas. L. M. Davidoff and J. Martin. J. Neurosurg. **12**:375-384 (July) 1955 [Springfield, Ill.].

Von Recklinghausen's disease in the form of multiple neurofibromatosis affecting not only peripheral nerves but cranial and spinal nerve roots has been demonstrated to show marked hereditary tendencies. Even when this disease, unaccompanied by widespread neurinomatosis, manifests itself only in the form of bilateral acoustic nerve tumors, it has been shown to be hereditary. Cushing and Eisenhardt, in their monograph on meningiomas, brought together from the literature reports of cases of multiple meningiomas and of neurinomas and meningiomas occurring in the same patient. The earlier history of one of the two patients cited here had been reported by Cushing. This patient was the father in the father and daughter team presented here. The patients had bilateral cerebellopontine neurinomas combined with meningiomatosis. Bilateral deafness was present in both patients; bilateral acoustic neurinomas were suspected in each. In the father a small tumor nodule in one cerebellopontine angle was found that, in addition to typical whorl formations, also showed areas of palisading suggesting a mixed type of tumor. The rest of his many small and large intracranial neoplasms were typical meningiomas. No postmortem examination was performed in the father. In the daughter a meningioma was removed from the thoracic spinal canal at the age of 15, and at 20 multiple posterior fossa meningiomas were verified at operation. At postmortem examination the undersurface of the dura mater bilaterally was studded with discrete as well as confluent almost countless meningiomas, in addition to which two larger tumors, one in each cerebellopontine angle, were found that histologically were neurinomas but contained whorls in areas suggestive of mixed neurinoma and meningioma in the same tumor, similar to the angle tumor reported in her father.

Electroencephalographic Changes in Antabuse Treatment. E. Pedersen. Ugesk. læger **117**:812-816 (June 23) 1955 (In Danish) [Copenhagen, Denmark].

More extensive use of electroencephalography before the start of Antabuse treatment and during the first weeks of the treatment is thought desirable. Investigations showed that in most cases changes in the electroencephalogram occur during treatment with 0.5 gm. Antabuse daily, both in normal persons and in chronic alcoholics. The changes are manifested by lower dominant rhythm and increased occurrence of low frequencies with increased and varied voltage, so that the curves often present a paroxysmal pattern. In some cases spikes appear and sometimes there are focal changes. The electroencephalographic changes appear to be independent of whether the curves were normal or abnormal before Antabuse treatment and are an expression of the toxic effect on the cerebrum, probably involving both the basal ganglions and cortex. The changes were least marked when low doses were given. The doses should be individualized and probably be set as low as possible. Permanent changes in the electroencephalogram in some cases may point to permanent organic injury. Antabuse lowers the convulsive threshold, as evidenced partly by the occurrence of spontaneous seizures and partly by the fact that in two cases, one of them in a normal person, signs of epileptic seizures occurred on provocation. Caution is urged in treating epileptics with Antabuse.

Epilepsia Tarda: Clinical Analysis. R. Müller. Nord. med. **53**:990-994 (June 23) 1955 (In Swedish) [Stockholm, Sweden].

From 1951 to 1953, 126 patients with epileptic seizures setting in after the age of 30 were treated in the Serafimer Hospital. The neurological status was negative. Neither history nor psychic or physiological examination gave reliable information as to the etiology of the attacks. The cerebrospinal fluid was normal except in one case. In 65 patients the seizures were focal type-generalized seizures with aura, psychomotor seizures, or jacksonian convulsions. Cerebral tumor was established in 14 cases and in three additional cases roentgenologic changes pointed to an expansive process. One of the verified tumors gave no roentgenologic changes; electroencephalographic changes and the clinical picture led to operation. Three patients had aneurysms. Of the 18 patients with jacksonian convulsions, 10 had a tumor or aneurysm. Electroencephalography was done repeatedly in all but 4 cases; focal changes were demonstrated in 38 cases and uncertain in 3, and epileptogenic activity was found in 17 cases. Pneumoencephalography was done in all but the 3 cases in which arteriography had revealed an aneurysm, and carotid angiography was performed in 84 cases, bilaterally in 31 of these. Fifteen of the 16 patients in whom roentgenogram showed an expansive process were operated on, and tumor was verified in 13 cases. Of 20 patients with grand mal only 3 had a tumor. In meningioma clinical analysis was more reliable than electroencephalography. Besides the expansive processes, angiopathy and trauma were the most common causes of late epilepsy. Cerebral angiopathy is difficult to establish and the diagnosis is most often a probability diagnosis.

Treatment of Tuberculous Meningitis with Particular Reference to the Intrathecal Tuberculin Reaction. H. M. Rennie and J. Read. Australasian Ann. Med. **4**:135-140 (May) 1955 [Sydney, Australia].

Rennie and Read describe observations on two patients with tuberculous meningitis, with particular regard to the treatment and the intrathecal tuberculin reaction. They feel that the accumulated evidence favors the abandonment of intrathecal therapy, and they now use the following therapeutic regime for adults: (1) streptomycin, given by intramuscular injection in a dose of 2 gm. per day until a definite response is established, followed by 1 gm. per day for 6 months and 1 gm. twice a week for at least another 6 months; (2) isoniazid, 300 mg. given orally per day for at least 12 months; and (3) corticotropin or cortisone, if any evidence of subarachnoid block appears. The first of their two patients, who was in a very early phase, made an uncomplicated recovery. The second patient had a longer history when she came under treatment, and though her cerebrospinal fluid findings improved slowly, she was still ill and had evidence of increased intracranial tension and commencing subarachnoid block after six weeks of treatment. In view of these findings, it was suggested by a neurological consultant that the intrathecal administration of streptomycin be given a trial. However, she became so much worse under this treatment that it was hurriedly abandoned. Corticotropin and cortisone completely reversed the ill-effects, and her clinical condition improved rapidly. Since that time her progress has been one of steady improvement. With regard to the behavior of the cerebrospinal fluid, the authors point out that Smith and Vollum in 1950 drew attention to the fact that with a regime of intrathecal and intramuscular administration of streptomycin high "spikes" of cells, containing 60% to 90% of polymorphonuclear cells, appeared in the cerebrospinal fluid at about the time when the organisms were disappearing from the cerebrospinal fluid. This common finding was considered to be associated with a chemical irritation of the meninges by the intrathecal administration of streptomycin. However, Swithinbank, Smith, and Vollum found that streptomycin injected into the normal subarachnoid space does not cause any noticeable cellular reaction. On the other hand, by the introduction of tuberculin into the subarachnoid space of Mantoux-positive control patients, they were able to reproduce the spikes of cells, with polymorphonuclear predominance, and a rise in protein content very similar to that seen in tuberculous meningitis treated by the intrathecal administration of streptomycin. They then regarded the cerebrospinal fluid pleocytosis in tuberculous meningitis as due to an endogenous tuberculin reaction set off by the tuberculoprotein of organisms killed by intrathecally administered streptomycin and not to the irritant effect of streptomycin itself. The authors regard the cerebrospinal fluid response in their own cases as a natural endogenous intrathecal tuberculin reaction, the more so since intrathecal streptomycin therapy was not used in one of their patients and only briefly in the second patient. They emphasize the apparent suppressive effect of corticotropin and cortisone.

PEDIATRICS

Studies in Sickle Cell Anemia: V. Sickle Cell Hemoglobin C Disease (Report of Two Cases in Siblings with Clinical and Genetic Observations and a Brief Review of the Literature). R. B. Scott and M. E. Jenkins. A. M. A. Am. J. Dis. Child. 90:35-42 (July) 1955 [Chicago].

The application of genetic, biochemical, and electrophoretic techniques to the study of sickle cell anemia has revealed that the condition is not a simple disease entity but is in reality a hemolytic syndrome that may be separated into specific subtypes depending upon the variety of abnormal hemoglobin present. The designation of sickle cell anemia is reserved for the type in which the genes responsible for sickling are homozygous. Statistically, this is the commonest variety. The second most frequently encountered type of sickle cell disease in American Negroes is apparently sickle cell-hemoglobin C disease and is due to the simultaneous presence in the person of the sickle cell gene and the gene responsible for C hemoglobin. The authors present observations on two siblings with sickle cell-hemoglobin C disease. The patients were Negro boys, aged 12 and 9 years respectively. The mother of these boys carries the sickle cell trait and the father carries the trait of C hemoglobin. One paternal uncle shows C trait, as does one of his three sons. Both boys had symptoms fairly early but have experienced a very mild course. The clinical picture of mild hemolytic anemia, infrequent pains, enlarged spleen, and numerous target cells on peripheral smear in a Negro patient whose blood exhibits the sickling phenomenon should immediately suggest the possibility of sickle cell-hemoglobin C disease. The diagnosis can easily be confirmed by paper electrophoresis. The disease is inherited in the same manner as the commoner homozygous sickle cell disease, with one parent contributing the sickling trait, the other the trait of hemoglobin C. In general, this subtype is milder than the commoner variety; however, cases of exceptional severity have been reported. Awareness of this new hemolytic syndrome is necessary in order to avoid confusion with similar entities. The first patient was thought to have the usual type of sickle cell anemia from the age of 5 to 12 years. The second patient had been considered a sickle cell trait case. Some of the thalassemia-minor-like cases observed in the Negro may represent hemoglobin C trait states (combination of normal and C hemoglobins). The benign hemoglobin C trait has been found to occur in about 2% to 3% of American Negroes. The blood smear may appear normal except for the presence of target cells. Sickle cell-hemoglobin C disease has a fairly characteristic clinical picture, namely, relatively mild crises, erythrocyte sickling, and high incidence of target cells on blood smears associated with an enlarged spleen. A definitive diagnosis can be made by the use of filter paper electrophoresis. Treatment is mostly symptomatic, and blood transfusions are rarely necessary.

Acute and Subacute Terminal Ileitis. Chérigié, Tavernier, Dupas and Raynal. Semaine hôp. Paris 31:2417-2427 (July 6) 1955 (In French) [Paris, France].

The authors performed radiographic examinations of the terminal ileum in 70 children in the active or convalescent stage of various diseases. They concluded that follicular hypertrophy is rare in normal children and that lymphoid hypertrophy of the terminal ileum should be considered a pathological manifestation. Ileocecal localization seems to reflect a primary disease; the authors found that most of their patients with infectious diseases (measles, scarlet fever, angina, or pneumonia) or parasitoses had considerable follicular hypertrophy with enlargement of the aggregate nodules and adenopathy sometimes visible roentgenologically. Many of the patients had a point of tenderness or pain over the appendix; this pseudoappendicitis so often seen before the appearance of an infectious disease is explained by the frequency of the lymphoid hypertrophy. Other diseases that are preceded or accompanied by hypertrophy are tuberculosis of the small intestine, regional ileitis (Crohn's disease), and typhoid. The authors believe that so-called primary mesenteric adenitis and common inflammatory follicular hypertrophy are in reality the same disease. Hypertrophy of the lymph nodes is common to both. The disease appears to be more severe in adults than in children. The differential diagnosis from Crohn's disease is almost impossible at the outset. During epidemics of infectious diseases, radiological examination should be made of patients with appendical pain in order to demonstrate the presence or absence of mesenteric adenitis so that unnecessary surgical intervention may be avoided.

Treatment of the Nephrotic Syndrome with Corticotropin (ACTH) and Cortisone: A Four-and-One-Half-Year Survey of Results with Short-Term Courses. W. Heymann, S. Spector, L. W. Matthews and D. J. Shapiro. A. M. A. Am. J. Dis. Child. 90:22-27 (July) 1955 [Chicago].

Sixty-four children with the nephrotic syndrome, whose ages ranged between 1 and 9 years, were observed by the authors between October, 1949, and April, 1954. The shortest period any child has been followed has been 14 months, and more than 50 have been followed for more than two years. Corticotropin was given by the intramuscular route in four divided doses in amounts of 60 to 80 units per 24 hours, usually for 10 to 12 days. When given intravenously, 15 units were given in 300 ml. of 5% dextrose by slow drip over 8 to 12 hour periods. Cortisone was used orally in doses of 150 to 200 mg. per 24 hours in three divided daily doses for 10 to 12 days. When diuresis occurred or if it failed to be noted by the eighth or ninth day, the dosage of the hormones was gradually reduced over a three to four day period. The 64 children received a total of 189 short-term courses of corticotropin or cortisone. Twelve are probably cured, 19 are in remission, in 16 the disease is still active, and 17 are dead. Diuresis was obtained in 81%. The incidence of diuresis did not significantly differ whether corticotropin was given by intramuscular or by intravenous injection or whether cortisone was used. The average length of remission after corticotropin therapy was 4.2 months and after cortisone, 2.6 months. The incidence of diuresis in patients who ultimately died in renal failure was 53%. Of 13 patients who failed to have diuresis two or more times, 11 have died in uremia. Complications such as azotemia and electrolyte disturbances were infrequent and reversible. Convulsions occurred six times during the period of therapy and were a sign of poor prognosis. Of 17 children who died, at least 14 died in renal failure. Ten of these had no hematuria, azotemia, or hypertension at the time of onset of treatment. This observation suggests that corticotropin or cortisone given in short-term courses does not affect the progression of the glomerular lesion. An ultimate mortality rate of approximately 35% is expected in this series.

A Study of Twins: Blood Groups and Other Data. R. J. Walsh and O. Kooptzoff. Australian J. Exper. Biol. & M. Sc. 33:189-198 (April) 1955 [Adelaide, Australia].

The primary purpose of the present work was to investigate the usefulness of blood groups in distinguishing uniovular from binovular twins. The opportunity was taken to compare differences in weights and lengths of the pairs according to the results of blood grouping, and maternal age and parity were also compared in the two groups. Blood samples were obtained from all twins delivered at the Royal Hospital for Women, Sydney, and at the King George V Memorial Hospital for Mothers and Babies, Sydney. Two or three drops of blood were obtained from a needle prick of the heel and mixed with approximately 1.5 ml. of physiological sodium chloride solution. The red blood cells were washed twice with this solution before use and were tested within 24 hours of collection. Tests were performed on every sample for the A_1A_2BO groups, the MNS system, and with anti-D, anti-C, anti-E, and anti-c of the Rh system. Tests were usually made for the Fy (a) antigen and on some occasions for the P, Le(a), Lu(a), and Kell antigens. However, only the results of the ABO, MNS, and Rh tests are considered in this paper. At the time of the blood groups test, the authors were not aware of the sex of the twins nor of their weight and length. This information, together with details of the maternal age and parity, was obtained later from the hospital records. Each of four factors (sex, ABO group, Rh group, and MNS group) distinguished a number of binovular twins, and each factor had approximately the same value. On the average, a single factor distinguished 34% of the pairs examined. Six different combinations of any two of these factors can be obtained, distinguishing on an average 53% of the pairs. The four combinations of three factors distinguish on an average 64%, while all four factors together distinguish 70%. The percentage of binovular pairs established (1) by sex alone was 30%; (2) by sex and ABO group was 54%; (3) by sex, ABO group, and Rh group was 65%; and (4) by sex, ABO group, Rh group, and MNS group was 72%. From theoretical considerations, it seems probable that the four factors used together distinguish almost all the binovular pairs. Determination of the ovular origin of human twins may be important in studying the susceptibility of genetically similar individuals to physical disorders and to psychotic and neurotic disturbances. In childhood and adult life, physical differences frequently permit recognition of the binovular nature of twins of the same sex, but such differences are usually not apparent in the neonatal period. Furthermore, the anatomy of placentas is sometimes difficult to interpret and is not always decisive.

OPHTHALMOLOGY

Retrolental Fibroplasia in the United Kingdom: A Report to the Medical Research Council by Their Conference on Retrolental Fibroplasia. Brit. M. J. 2:78-82 (July 9) 1955 [London, England].

In October, 1951, when very little was known of the etiology and incidence of retrolental fibroplasia, a detailed investigation was set in train by the Medical Research Council. Premature baby units in hospitals spread throughout the United Kingdom were asked to complete a questionnaire relating to each mother during her pregnancy and to the treatment and development of the baby up to the age of 6 months. Observations were recorded at 17 such units during the period Oct. 1, 1951, to May 31, 1953. During the 20 months of the inquiry, 1,999 babies of 4 lb. (1,800 gm.) or under entered the nurseries, and the 1,095 of them who survived for at least two months form the basis of this report. Of these 1,095 babies, 84 (7.7%) showed evidence of a retinopathy, the criterion being the presence of neovascularization in the fundus, which was found during routine ophthalmoscopy performed at regular intervals on all the children. In 39 of the 84 infants there was a subsequent regression, or return to normal fundi; in 45 there was blindness, implying one or both eyes permanently affected, with almost certain severe loss of vision. It was found that the cause of prematurity and maternal factors other than vaginal bleeding did not influence the subsequent development of the retinopathy. Boys were more often affected than girls; the main reason for this appears to be that they are more immature than girls for a given birth weight. The nurseries showed wide variations in their use of oxygen and, in general, corresponding variations in the incidence of the disease. The use of oxygen predisposed to the development of a retinopathy. Except in two cases, at least five days' treatment with oxygen was required to produce the disease; and the likelihood of a baby getting the disease increased as the treatment with oxygen was prolonged. There are many other variables to be taken into account, but nurseries in which little oxygen was given and which were free from cases of progressive retinopathy did not, on the average, experience survival rates inferior to nurseries using more oxygen. Clinical signs of anoxia at and after birth were associated with a higher incidence of retinopathy, but on the average more oxygen was given to anoxic babies.

Incidence of Retrolental Fibroplasia in England and Wales in 1951. J. T. Boyd and K. M. Hirst. Brit. M. J. 2:83-85 (July 9) 1955 [London, England].

Particulars were obtained from all local authorities in England and Wales of infants born in 1951 having a birth weight of 4 lb. 6 oz. (2,000 gm.) or less and surviving at least two months. The survey provided data on 6,926 infants. The condition of the eyes was ascertained and 127, or 1.83%, of the infants were found to have retrolental fibroplasia. Not a single case of retrolental fibroplasia was found among the 797 infants who were born at home and remained there. This absence of cases among the home infants supports the view that the risk of developing retrolental fibroplasia is closely associated with some factor connected with hospitalization. Applying the specific incidence rates by sex and birth weight observed in the total population of infants to the number of infants in each of the corresponding subgroups of the home population, it was found that as many as seven or eight cases would have occurred among the infants born at home and not transferred to hospital, if they had been subject to the same risks as the whole population. The incidence of retrolental fibroplasia was closely related to birth weight, declining steeply with increasing birth weight. The incidence was higher in males than in females, but this difference may be due to male babies being less mature than female babies of the same weight. Twin babies showed the same incidence as single babies. Considerable regional variability was observed.

Retrolental Fibroplasia: Three Cases in Puerto Rico. G. Pico. Bol. asoc. méd. Puerto Rico 47:288-296 (July) 1955 (In Spanish) [Santurce, P. R.].

Retrolental fibroplasia is the most frequent cause of blindness among infants of certain countries in which the care of premature infants includes prolonged exposure of the infant to oxygen at high concentrations in incubators. The disease develops in 98% of premature infants, weighing approximately 4 lb. (1,800 gm.) at birth and in 2% of infants having normal weight at birth. Usually the disease is bilateral but may be unilateral. The eyes appear normal immediately after birth. Constriction of the retinal vessels may or may not appear in the first three weeks of life of the infant. The disease follows its course in an active period of three months followed by the cicatricial period. The early retinal changes are first clinically noted about the end of the third week. They consist of dilatation and tortuosity of the retinal vessels, edema, hemorrhages, elevation of the retina, and new blood vessel formation, followed by some other changes up to complete detachment of the retina and diffusion of angioblastosis. After this period, permanent damage manifests itself by the presence of opaque masses of detached retina and vascularized fibrous tissue behind the lens. The differential diagnosis is made from retinoblastoma, persistent primary hyperplasia of the vitreous and pseudoglioma, so-called metastatic retinitis, or purulent endophthalmitis. The disease may appear in infants born at full term who did not have oxygen therapy. In these infants, the sudden increase of oxygen from 50% in the arterial blood of the fetus to 90% at birth plus a retinal lability seem to be the cause of the disease, whether the infants are premature or full-term. No cases of retrolental fibroplasia have been reported from Latin American countries and from Puerto Rico, all countries in which incubators are few and the infants are rarely exposed to high concentrations of oxygen. The author reports three cases in Puerto Rican children whom he observed in the course of the last 10 years in the Clinic of Ophthalmology of the University of Puerto Rico. Two of the patients are prematures and one was born at full term and with normal weight. None of the patients received oxygen therapy in the neonatal period. The children are blind with the typical damage of retrolental fibroplasia.

Intermittent Exophthalmos from Orbital Varices. J. A. Sená. Semana méd. 62:805-810 (June 9) 1955 (In Spanish) [Buenos Aires, Argentina].

The subject of this report, a man 24 years old, was normal up to the age of 20, when he began to notice transient exophthalmos of the left eye following any violent movement of the head or physical effort. Exophthalmos disappeared on discontinuation of the effort. The eye was enophthalmic in normal conditions. Acute bending of the patient's head produced exophthalmos of 20 mm. in the left eye, whereas the right eye did not change. The condition disappeared as soon as the head was turned to the normal posture. There was no ocular pain, dilatation of the facial veins, cutaneous or intracranial varices, or supernumerary rib. The eyes and vision were normal. The author states that intermittent exophthalmos is always unilateral and nearly always on the left side (90% of the cases). The condition follows a benign course when orbital varices are uncomplicated. Prophylactic treatment consists of preventing postural changes and physical efforts. Progression of the condition, as shown by recurrences and progressive degree of exophthalmos or ocular pain, calls for medical therapy consisting of perivascular intraorbital injections of sclerosing substances to cause obliterating periphlebitis of the varices. For this purpose, Raverdino's method and technique are of value. During the occurrence of provoked exophthalmos a 4 cm. needle is introduced into the lower wall of the orbit and a perivascular injection of 2 cc. of a solution containing quinine hydrochloride, 4 gm., urethan, 2 gm., and distilled water, 30 cc., is given. The injection is followed by a transient acute pain in the orbit and an acute inflammation of the involved half of the face. This is controlled in two days by application of cold compresses. One injection is sufficient; if it is necessary to administer a second injection, it can be given one week after the first.

THERAPEUTICS

Antiarrhythmic Action of Ambonestyl. V. Lanzoni and B. B. Clark. Circulation Res. 3:335-343 (July) 1955 [New York].

The antiarrhythmic activity of Ambonestyl, 2-diethyl-aminoethyl-isonicotinamide (MC 4112), was compared with that of procaine amide in a series of experiments on dogs. Ambonestyl was shown to be as effective in suppressing experimental ventricular tachycardia following coronary occlusion as procaine amide; pharmacologically, however, it is more specific because (1) it does not depress cardiac conduction, (2) it does not elevate the ventricular electrical threshold, and (3) it produces less hypotension. This last finding is clinically interesting, because the frequency with which procaine amide produces hypotension when administered intravenously limits its usefulness. Comparison of the relative arrhythmia-suppressive potency of the two products indicated that the activity of Ambonestyl was roughly equivalent (on a weight basis) to that of procaine amide; the duration of its action, on the other hand, seemed to be longer. The over-all toxicity of Ambonestyl is less than that of procaine amide. The fact that cardiac conduction is not depressed by Ambonestyl is important, because depression of conduction may occur with the use of both procaine amide and quinidine, especially in patients with intraventricular conduction disturbances. A slight increase in the refractory period following the administration of Ambonestyl was the only effect demonstrated on normal heart tissue. These findings suggest that neither elevation of the ventricular electrical threshold nor depression of cardiac conduction is essential to antiarrhythmic action. Examination of Ambonestyl for other pharmacological actions revealed that it has no local anesthetic, no adrenolytic or sympatholytic, no atropine-like, and no antihistaminic activity. Vagal depressing and ganglionic blocking actions were evident only with large doses (about three times those of procaine amide). Preliminary studies in man, now in process of publication, have so far corroborated these experimental findings.

Effectiveness of Aramine in the Treatment of Shock. J. H. Moyer and H. L. Beazley. Am. Heart J. 50:136-144 (July) 1955 [St. Louis].

Vasopressor agents have proved of value as collateral therapy in shock, not only because they help to restore the blood pressure but because some of these agents have proved effective in improving depressed renal function. Levo-1-(M-hydroxyphenyl)-2-amino-1-propanol, which is known as Aramine, is a synthetic sympathomimetic amine. It has a more prolonged effect than arterenol (norepinephrine). Twenty patients with various types of clinical shock were given Aramine by constant intravenous infusion. The concentration varied from 50 to 200 mg. per liter, depending upon the pressor response. The rate of infusion was varied (between 2 and 6 cc. per minute) as necessary in order to avoid excessive fluid administration. In 4 of the 20 patients, arterenol in concentrations varying from 4 to 16 mg. per liter was used in combination with Aramine in an attempt to maintain a constant blood pressure without administering large amounts of fluid. The other patients were treated alternately with Aramine and arterenol (for shorter periods of time) for comparative purposes. Renal hemodynamic studies were done on several patients using inulin to determine glomerular filtration rate and *p*-aminohippurate to determine renal plasma flow. The patients included 14 men and 6 women, who ranged in age from 23 to 93 years. Shock was due to acute myocardial infarction in three patients, cerebrovascular accident in four, upper gastrointestinal hemorrhage in one, bleeding esophageal varices in two, serum sickness in one, postpartum hemorrhage in one, uremia in three, Weil's disease in one, sickle cell crisis in one, carcinomatosis in two, and anesthesia induction in one. Six of the patients received whole blood transfusions in varying amounts prior to the vasopressor administration. It is believed that these patients probably would have died had not vasopressor therapy been available. Nineteen of the patients had a prompt and satisfactory vasopressor response within 8 to 10 minutes. The unresponsive patient was admitted in shock of approximately two and one-half hours' duration. Despite rapid intravenous administration of Aramine there was no significant blood pressure response, and the patient died 13½ hours later. Vasopressor therapy was continued for from 5 to 231 hours. When the responses to Aramine and arterenol were compared, using each drug alone, it became apparent that on a weight basis Aramine was only about 0.05 to 0.04 as potent as arterenol when administered by continuous intravenous infusion to patients in shock. However, the blood pressure was much easier to maintain at a constant level than with arterenol. Thus it seems to have some advantage over arterenol. No sloughs resulted from its intravenous use. Compromised renal function was improved in that there was an increase in glomerular filtration rate, renal blood flow, and urinary output.

PATHOLOGY

Glomerulotubular Nephrosis Correlated with Hepatic Lesions: III. Production of Acute Glomerulotubular Nephrosis in the Rabbit by Means of Hepatic Surgery. C. N. Crowson, R. H. More and G. Frkovich. A. M. A. Arch. Path. 60:85-94 (July) 1955 [Chicago].

In the second of a series of three reports on glomerulotubular nephrosis with hepatic lesions (reported in the same issue) a close correlation was established between glomerulotubular nephrosis and structural changes in the liver. The hepatic changes consist of acute and chronic lesions and vary from severe fatty metamorphosis, cirrhosis, and acute edema, through all stages of atrophy and minor necrosis to massive hepatic necrosis. The hypothesis is proposed that vasopressor materials accumulate in the systemic circulation during periods of hepatic insufficiency and produce renal ischemia. The correlation is felt to comprise part of the hepatorenal syndrome, and it is recommended that the syndrome, already nebulous and ill-defined, be extended to include these related phenomena. The third report describes an attempt to reproduce experimentally correlated hepatic and renal damage corresponding to the associated hepatic and renal lesions reported in human autopsy material in part 2 of this series. This was done by means of temporary occlusion of the hepatic vasculature in rabbits. The object of this procedure was to produce a state of acute hepatic insufficiency without jaundice. Glomerulotubular nephrosis was found to develop in 90% of these animals. A rather large number of the rabbits used in this investigation (43%) showed preexisting hepatic lesions of varying types and duration. These hepatic changes showed a 95% correlation with degenerative renal changes, causing major reorganization of the experimental groupings. A lesion identical with acute glomerulotubular nephrosis has been produced in two rabbits by direct renal ischemia. The proposed ischemic etiology of glomerulotubular nephrosis has been discussed in the light of the associated hepatic disorders, with the following possible sequence of events: hepatic insufficiency developing in the presence of a variety of lesions; the insufficient liver failing to detoxify some potent vasospastic material in the circulation; and thi agent producing selective arteriospasm in small renal vessels. *The Masson trichrome stain is recommended by the authors for* use in carrying out investigations of acute degenerative lesions of the kidney.

Virilizing Tumors of the Ovary: Anatomopathologic Study. P. Laffargue. Presse méd. **63**:959-961 (June 22) 1955 (In French) [Paris, France].

The author believes that the classic classification of arrhenoblastomas made by Robert Meyer in 1930 should be revised, since it is now established that the ovary normally secretes androgens. Virilizing tumors should be considered on the same basis as feminizing tumors, and it should be acknowledged that they arise from cells whose presence is not abnormal. There are male tumors of the ovary that may be regarded as tumors of the genital blastema. These contain epithelial cords and interstitial cells. Joint or isolated variations in these two types of tissue give rise to the various types of arrhenomas, mixed and pure. The mixed forms are less differentiated and the pure forms have a high degree of maturity; they contain Sertoli or Leydig cells. These pure forms are found in dystrophy or hyperplasia of the ovary in exact correspondence. This shows that the ovary normally has androgenic sources of which the pathological manifestations are hyperplasia and neoplasia, in the same way that it has estrogenic sources that are subject to the same pathological manifestations.

Exfoliative Cytology and Pulmonary Cancer: A Histopathologic and Cytologic Correlation. H. J. Spjut, D. J. Fier and L. V. Ackerman. J. Thoracic Surg. **30**:90-107 (July) 1955 [St. Louis].

Although it is generally accepted that the examination of pulmonary secretions for cancer cells is valuable, the authors attempted to investigate (1) the limitations of this procedure; (2) what information other than the report of positive, suspicious, or negative is gained by cytological examinations. They reviewed 501 cases of patients with histologically proved pulmonary cancers who were admitted to Barnes Hospital between July, 1948, and April 1, 1953. For tissue confirmation of cancer there were 318 bronchial biopsies, 95 other biopsies, 163 pneumonectomies, 35 lobectomies, 126 thoracotomies for exploration, and 35 autopsy examinations. In each of the patients at least one sputum or bronchial washing was studied for cancer cells. Thus, there were 905 sputum examinations for 424 of the cases, and 364 bronchial washings for 343 cases. Many patients had both types of examination. The cytological examinations yielded 243 positive, 53 suspicious, and 205 negative results. Thirty-one and six-tenths per cent of the bronchial washings were positive, and 27.1% of the sputa were positive. On a case basis the over-all percentage of positive reports was 57.8% and with an optimum number of specimens, 76.6%. The optimum number of sputa and bronchial washings for study was found to be three. Of the 318 bronchial biopsies 211 or 66.3% were positive. Only 28% of the positive biopsies were in the operable cases. The lower lobes yielded the highest percentage of positive smears (bronchial washings). The highest percentage of positive sputa was obtained from the left upper lobe. Cytological examinations are of value in the diagnosis of peripheral pulmonary cancers. Lesions 2 to 3 cm. in diameter and those larger than 7 cm. produced the highest percentage of positive smears. Patients with positive hilar and bronchopulmonary nodes yielded a higher percentage of positive bronchial washings than did those with negative nodes. Sputum examinations remained much the same for the two groups. Positive smears were obtained in 56.1% of the operable and 59% of the inoperable cases. With a positive biopsy, the number of operable cases decreased notably. In 59 of the operable cases, the cytology was the only positive tissue examination prior to operation. Thirteen frozen sections (with 11 positive) were asked for in these cases. Thus, 48 of the patients underwent resection with cytology as the sole tissue diagnosis. Typing of the positive smears was 79.3% accurate. Epidermoid carcinomas were correctly typed in 89.2% of instances, undifferentiated carcinomas in 76.2%, and adenocarcinomas in 39.3%. Two bronchiolar carcinomas were accurately typed from the smears.

RADIOLOGY

Tissue Injuries After Roentgen and Radium-Irradiation: II. Clinical Aspects. C. F. Koch. Nederl. tijdschr. geneesk. 99: 1742-1746 (June 11) 1955 (In Dutch) [Haarlem, Netherlands].

This is one of a series of three papers on tissue damage from irradiation, the other two dealing with the radiological and pathological aspects respectively. The clinical aspects reviewed in this paper are based on observations on 80 patients, in 6 of whom carcinomatous degeneration resulted. Often the patient himself is responsible for skin damage from irradiation, in that he fails to admit to a new physician that he previously received irradiation therapy. The author comments on the appearance of the lesions and the changes that they undergo, such as secondary infections and malignant degeneration. He also mentions the long periods that may intervene between the original irradiation and the development of carcinoma; in one of the patients observed by him this interval was 30 years. Irradiation is very damaging in young children, growing bone tissue being particularly susceptible. The author concludes that the number of patients being damaged by irradiation is greater than is generally known. Ray damage has not been restricted to the early era of irradiation therapy, but damage by excessive dosage still occurs today. In the majority of patients in whom the author observed ray lesions irradiation therapy had been given for nonneoplastic lesions such as for hemangiomas, nevi, warts, articular pains, tuberculous lymphomas, and psoriasis. Possibly many patients who were irradiated for neoplastic lesions died before irradiation necrosis became manifest. Nonneoplastic lesions that will respond just as well to treatments other than irradiation should not receive irradiation therapy. Surgical treatment is the only effective treatment for lesions caused by irradiation. Modern plastic surgery produces results that are not disfiguring.

Experiences with Hysterosalpingography. L. Öhlinger. Wien med. Wchnschr. **105**:451-452 (June 4) 1955 (In German [Vienna, Austria].

Hysterosalpingography was performed with the aid of a viscous, water-soluble contrast medium [a diiodide pyridone compound with addition of a surface anesthetic and sodium carboxymethylcellulose (Ioduron S)] in 81 sterile women in the course of 11 years. Of the 81 patients, 47 (58%) had primary sterility and 34 (42%) secondary sterility. The average age of the patients was 32 years. In 29 women tubal obstruction was shown to be the cause of the sterility and in the remaining 52 at least one or both oviducts were patent. Of the 29 women with bilateral tubal obstruction, the tubes were occluded at the uterine end in 8 women (27%), at the isthmus in 5 (19%), and at the ampulla in 15 (50%); peritubal covering was shown in one (4%); and 18 women (22.22%) became pregnant after the hysterosalpingography. These results suggest that a therapeutic effect of hysterosalpingography may be considered besides its diagnostic value.

ANESTHESIA

Effect of Premedication with Chlorpromazine. *O. Oljelund* Nord. med. **53**:734-736 (May 5) 1955 (In Swedish) [Stockholm Sweden].

Laparotomy was done in 200 patients, of whom 100 received premedication according to Gordh, with 50 mg. chlorpromazine given intramuscularly together with an average of 4 mg. of morphine and 0.3 mg. of atropine. The 100 controls received preoperatively an average of 9 mg. of morphine and 0.4 mg of scopolamine, 2 mg. of dilaudid, and 0.3 mg. of atropine It was found that chlorpromazine reduced the amount of barbiturate necessary during anesthesia by 21%; the postoperative course during the first five hours was uneventful; and the frequency of vomiting was reduced by 36% and the amount of analgesics needed by 38%. Hypotension, sometimes associated with nausea, occurred in 10 cases but did not affect the operative or postoperative course.

QUERIES AND MINOR NOTES

TING ACTIVE YEAST DAILY

THE EDITOR:—*A patient is fond of eating active yeast several imes daily and claims that he feels better with this food upplement; however, several years ago active yeast was ound by certain investigators to use up some of the vitamin ontained in the food passing through the intestine. How nuch vitamin is destroyed by active yeast organisms in the ntestine? Is it sufficient to justify the change from active yeast o inactive yeast as a source of essential nutritional elements, r does it make slight difference? Does active yeast reduce ntestinal putrefaction?*

George A. Ury, M.D., National City, Calif.

NSWER.—There is no question but what active yeast inter- es with the absorption of thiamine, not only from the yeast lf but the thiamine supplied in the food. Undoubtedly the ng yeast cells absorb thiamine and prevent its absorption by host. This has been clearly demonstrated in human subjects Garber and co-workers (*J. Nutrition* 38:225, 1949). Whether amine deficiency will be produced due to the consumption of ive yeast will depend on the amount of yeast consumed and v frequently it is consumed. The safest procedure would be process the yeast in such a way as to destroy the vitality of cells. This treatment would also render the other vitamins the yeast available to the body. It is doubtful that a general ement can be made that active yeast reduces intestinal refaction. The intestinal microflora are so complex that erent effects would undoubtedly be obtained under different ditions.

TRASONIC THERAPY

THE EDITOR:—*A veterinarian who has severe bronchial sthma insists on taking ultrasonic sound wave therapy to he chest for his asthma. This I am very reluctant to do in iew of the potentialities of this type of therapy and the parsity of clinical reports on its use in the treatment of sthma. Kindly advise.*

M.D., New Mexico.

NSWER.—There is no rational explanation nor reason to ect, nor are there adequate controlled studies reported to nonstrate, that ultrasonic diathermy is useful in the treatment bronchial asthma. On the other hand, the application of ultra- ic diathermy for therapeutic purposes is contraindicated ut the heart and large autonomic plexus, such as those found he chest.

OPHYLAXIS OF RHEUMATIC FEVER

THE EDITOR:—*Please give recommendations as to drug and losage for prophylaxis of rheumatic fever, both for an acute treptococcic infection and also for long-range seasonal herapy in an individual who is sensitive to both sulfonamides nd to penicillin.*

H. Edward Hengen, M.D., Pattonville, Mo.

NSWER.—In the presence of a definite sensitivity to penicillin the sulfonamides, the use of tetracycline (Achromycin) is icated. However, this drug is less effective than penicillin in dicating streptococci, decreasing antistreptolysin formation, preventing rheumatic fever. The average dose in the treatment of streptococcic infection is 10 mg. per pound of body weight, in four divided doses daily, for two days. This is followed by half the amount for a total of 10 days. For the prevention or prophylaxis of streptococcic infection with Achromycin, 2 mg. per pound of body weight should be given daily and continued to the age of 18, in a child. In patients above the age of 18, it should be continued for at least five years following the last attack.

ACUTE BACTERIAL ENDOCARDITIS

TO THE EDITOR:—*An 11-year-old boy has an interventricular septal defect. In December, 1954, he had mumps, and he never seemed to regain his former health. He was first seen on Feb. 2, 1955, because of malaise and easy fatigue. In addition to the typical Roger murmur and thrill, there was some pallor but no fever. The spleen was enlarged four fingerbreadths below the left costal margin. No petechiae were noted. Laboratory reports revealed the hemoglobin level was 68%, white blood cell count 8,150 per cubic millimeter, and red blood cell count 3,350,000 per cubic millimeter. Two weeks later, although he said he felt a little better, the patient was hospitalized, and examination again was essentially unchanged. His parents stated that for the past day he had run an intermittent afternoon and evening fever, but his temperature was always normal in the morning. Urinalysis was normal and sedimentation rate 12 mm. in one hour. The white blood cell count was 10,200 per cubic millimeter, hemoglobin level 70, and red blood cell count 4,120,000 per cubic millimeter. Differential revealed stab forms 1, segmented cells 42%, lymphocytes 55%, and monocytes 2%. Heterophil and agglutination tests were negative. During 10 days in the hospital, daily blood cultures were obtained, and to date they are all negative. There was a daily afternoon and sometimes evening temperature as high as 102.6, but usually averaging between 100 to 101. When discharged, the patient's sedimentation rate had increased to 28 mm. in one hour and there was a slight change in differential, with 3 stab forms, 51 segmented cells, 42 lymphocytes, and 4 monocytes. He felt better while in the hospital, and it was thought that his spleen decreased slightly in size. Chest x-ray was normal. One week after discharge his hemoglobin level was 70%, red blood cell count 4,160,000 per cubic millimeter, and white blood cell count 14,550 per cubic millimeter. He no longer ran an afternoon temperature but did have a low-grade temperature elevation each evening. No antibiotics have been given. The patient continues to gradually feel a little better. Is a diagnosis of subacute bacterial endocarditis justified? If so, what antibiotics would be suggested?*

M.D., South Dakota.

ANSWER.—Concerning the 11-year-old boy, this consultant believes that a patient with known congenital malformation of the heart and unexplained irregular fever of long duration, a large spleen, and an unexplained anemia should be treated for subacute bacterial endocarditis even in the absence of a positive blood culture. He should have a careful neurological examination to rule out the question of a brain abscess and then should be treated with large doses of penicillin, at least a million units a day for a week. If this ends his fever he should be given a six weeks' course of penicillin in large doses. If the above treatment for a week reduces his fever but does not cure it, the dose should be doubled or tripled and may be increased up to 10 million units per day. If that is successful, treatment with such doses should be given. If it has no effect, erythromycin should be tried, 200 mg. six times a day for a week, and, if that is effective, treatment continued for six weeks.

MYCOSIS

EDITOR:—*In a man 25 years of age the diagnosis of tomycosis was made by tissue examination of two pieces ssue taken from his back and buttocks in September, 1954. a while he had a cough, with some sputum, and had r for two months. X-ray examination of the chest showed ea in the left hilus the size of a 25-cent piece. The last y, taken Jan. 22, was negative. This patient has gained ght, has no fever, and does not cough or spit up. He was ted with saturated solution of potassium iodine. He took drops three times a day for four months and is now taking drops three times a day. What tests can I give to this man etermine if he is free of blastomycosis?*

Wallace D. English, M.D., Cardwell, Mo.

NSWER.—In blastomycosis, as in any other infectious loma, such as tuberculosis or syphilis, it is impossible to mine whether the patient does or does not harbor living -organisms after clinical cure has been achieved. In the of blastomycosis, one obtains the best orientation from complement-fixation test. For technique, specificity, and see Conant and others (Manual of Clinical Mycology, hia, W. B. Saunders Company, 1954). If the test is ve, treatment can be discontinued because negative com- -fixation test indicates inactivity of the disease. However, tient should remain under observation for many years, and complement-fixation test should be repeated periodically. blastomycin skin test usually remains positive after clinical like the tuberculin test in tuberculosis. It has been found a positive skin test combined with a negative complement- tion test is a prognostically favorable sign.

TO OBTAIN SERUM FROM CLOTTED BLOOD

THE EDITOR:—*A blood sample withdrawn from a young regnant woman clotted solidly as soon as it was transferred rom the syringe to a glass tube. There was no separation hatsoever of serum from the clot. The laboratory reported hat no readings could be taken. On a second sample an tempt was made to separate serum from clot by centrifugation after refrigeration but to no avail. Can you suggest a ethod for obtaining a serum sample to be used for blood type, Rh, and serology tests?*

Thomas N. Geracioti, M.D., Spencer, Ohio.

ANSWER.—After the blood has clotted, gently rim the clot th an applicator stick and centrifuge at high speed. This may ve to be repeated once or twice but should provide serum for ood type, Rh, and serology tests. If necessary the tests can performed on oxalated blood by washing the cells with line solution. A platelet count should be done, as a thrombo- topenia may account for the absence of clot retraction. If y, blood may be drawn in siliconized syringes and in- into siliconized tubes, centrifuged, and then allowed to at room temperature or in the refrigerator for approxi- tely two hours, at which time the blood will clot.

ARBON TETRACHLORIDE POISONING

O THE EDITOR:—*Has carbon tetrachloride poisoning, either chronic or acute, ever been proved to cause any type of insanity or mental disturbance?*

John T. Bate, M.D., Louisville, Ky.

ANSWER.—Prolonged psychotic states are rare as a result of n tetrachloride poisoning and perhaps do not occur at all. Neurological damage is more in evidence chiefly from damage to the optic nerve. However, in acute intoxication from carbon tetrachloride many mental symptoms have arisen and, in fact, are quite commonplace. In his book "Poisoning" (New York, Paul B. Hoeber, Inc., 1952) von Oettingen states the situation: "Acute carbon tetrachloride poisoning is dominated by symptoms from the central nervous system. The patient suffers from dizziness, inebriation, mental confusion, nervousness, and, less frequently from loss of memory. He may become delirious and suffer from convulsive seizures. Finally he becomes unconscious, stuporous, and comatose. In prolonged poisonings peripheral neuritis may develop with pareses, paresthesias, anesthesias, and tremors. The reflexes may be exaggerated or decreased. Vestibular disturbances may be present. Not infrequently the vision is blurred and there may be diplopia, amblyopia, and amaurosis."

FETOR HEPATICUS

TO THE EDITOR:—*Please describe fetor hepaticus. Is it usually accompanied by excessive dryness of the mouth?*

Arthur R. Timme, M.D., Los Angeles.

ANSWER.—To describe a smell in words is possible only by the use of analogy. This is of little help if the reader is not familiar with the odor to which fetor hepaticus is compared. Descriptions one finds in medical writings include the terms "rancid," "sour-sweet," "pungent," "like the smell of new mown hay," and perhaps the most remarkable is likening the smell to that of a nest of mice freshly turned up in a barn. The fact remains that to describe color to the colorblind, or music to the tone deaf, or fetor hepaticus to someone who has never smelled it is a literal impossibility. The material responsible for this odor is probably a complex chemical compound of the piperidine group. The smell is very nearly like but not identical with the odor of α-methylpiperidine. This material is found in high concentration in the urine of patients with severe parenchymal liver disease who have fetor hepaticus, less often in the urine of patients with obstructive jaundice. In fact it occurs in normal urine but in very much smaller amounts than in urine from patients who exhibit fetor hepaticus clinically. Fetor hepaticus is not usually or frequently associated with excessive dryness of the mouth. Such dryness may result from mouth breathing in patients who have coma along with fetor.

REACTION TO HORSE SERUM DURING PREGNANCY

TO THE EDITOR:—*Is there any evidence that a serious reaction to horse serum and the treatment of this with 200 mg. of cortisone daily for five days would have deleterious effect when occurring during the first month of pregnancy?*

M.D., California.

ANSWER.—Serious serum reactions have occurred in pregnancy without adversely affecting the fetus. Cortisone has been administered in amounts of 200 mg. daily for longer periods than five days in pregnancy without apparent harm to either the mother or fetus.

VISUAL LOSS FOR COMPENSABLE EYE INJURIES

TO THE EDITOR:—*The first part of the answer to Dr. Holohan's query in* THE JOURNAL, *April 9, 1955, page 1360, reveals a striking disparity in current evaluations of the Snellen notation and points up anew the need for a sound and equitable procedure for the solution of this problem. Having in earlier communications outlined the rationale establishing the Snellen symbol as inherently a true fraction, to arrive now at the actual measure of the intrinsic values connoted by the Snellen visual expression one must recognize that by the very nature of things it is not the fraction, i. e., visual angle itself, being dealt with, as set forth in the depicted table, but instead the subtended surface area of this fraction or angle. The principle of construction of the Snellen symbol is two-dimensional, the projected test object having height and width of equal size, viz., all four sides subtended by the same visual angle in minutes of arc; hence, in the final analysis, concern obviously is with the value of the area of some specific square, either that of the whole or of a related part. When given, then, as previously shown, any one dimension or aliquot part thereof squared, the resulting figure will represent the value sought. The evolution of an objective formula, such as this, is sound and correct, and a visual efficiency rating based on the square and not the linear unit as the determinant of Snellen visual values is, besides, a valid and appropriate concept.*

BLASTOMYCOSIS

To the Editor:—*In a man 25 years of age the diagnosis of blastomycosis was made by tissue examination of two pieces of tissue taken from his back and buttocks in September, 1954. For a while he had a cough, with some sputum, and had fever for two months. X-ray examination of the chest showed an area in the left hilus the size of a 25-cent piece. The last x-ray, taken Jan. 22, was negative. This patient has gained weight, has no fever, and does not cough or spit up. He was treated with saturated solution of potassium iodine. He took 90 drops three times a day for four months and is now taking 60 drops three times a day. What tests can I give to this man to determine if he is free of blastomycosis?*

Wallace D. English, M.D., Cardwell, Mo.

Answer.—In blastomycosis, as in any other infectious granuloma, such as tuberculosis or syphilis, it is impossible to determine whether the patient does or does not harbor living micro-organisms after clinical cure has been achieved. In the case of blastomycosis, one obtains the best orientation from the complement-fixation test. For technique, specificity, and literature see Conant and others (Manual of Clinical Mycology, Philadelphia, W. B. Saunders Company, 1954). If the test is negative, treatment can be discontinued because negative complement-fixation test indicates inactivity of the disease. However, the patient should remain under observation for many years, and the complement-fixation test should be repeated periodically. The blastomycin skin test usually remains positive after clinical cure, like the tuberculin test in tuberculosis. It has been found that a positive skin test combined with a negative complement-fixation test is a prognostically favorable sign.

HOW TO OBTAIN SERUM FROM CLOTTED BLOOD

To the Editor:—*A blood sample withdrawn from a young pregnant woman clotted solidly as soon as it was transferred from the syringe to a glass tube. There was no separation whatsoever of serum from the clot. The laboratory reported that no readings could be taken. On a second sample an attempt was made to separate serum from clot by centrifugation after refrigeration but to no avail. Can you suggest a method for obtaining a serum sample to be used for blood type, Rh, and serology tests?*

Thomas N. Geracioti, M.D., Spencer, Ohio.

Answer.—After the blood has clotted, gently rim the clot with an applicator stick and centrifuge at high speed. This may have to be repeated once or twice but should provide serum for blood type, Rh, and serology tests. If necessary the tests can be performed on oxalated blood by washing the cells with saline solution. A platelet count should be done, as a thrombocytopenia may account for the absence of clot retraction. If necessary, blood may be drawn in siliconized syringes and injected into siliconized tubes, centrifuged, and then allowed to stand at room temperature or in the refrigerator for approximately two hours, at which time the blood will clot.

CARBON TETRACHLORIDE POISONING

To the Editor:—*Has carbon tetrachloride poisoning, either chronic or acute, ever been proved to cause any type of insanity or mental disturbance?*

John T. Bate, M.D., Louisville, Ky.

Answer.—Prolonged psychotic states are rare as a result of carbon tetrachloride poisoning and perhaps do not occur at all. Neurological damage is more in evidence chiefly from damage to the optic nerve. However, in acute intoxication from carbon tetrachloride many mental symptoms have arisen and, in fact, are quite commonplace. In his book "Poisoning" (New York, Paul B. Hoeber, Inc., 1952) von Oettingen states the situation: "Acute carbon tetrachloride poisoning is dominated by symptoms from the central nervous system. The patient suffers from dizziness, inebriation, mental confusion, nervousness, and, less frequently from loss of memory. He may become delirious and suffer from convulsive seizures.
